

# Lecture 2b: Indirect Detection of Dark Matter

Ultra High Energy & Cosmic Rays

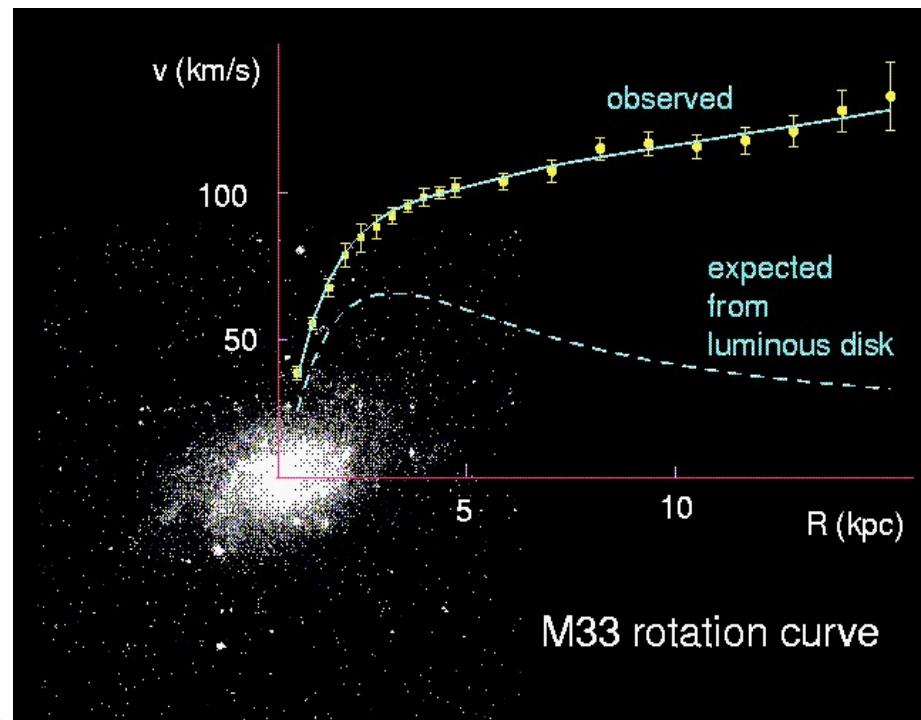

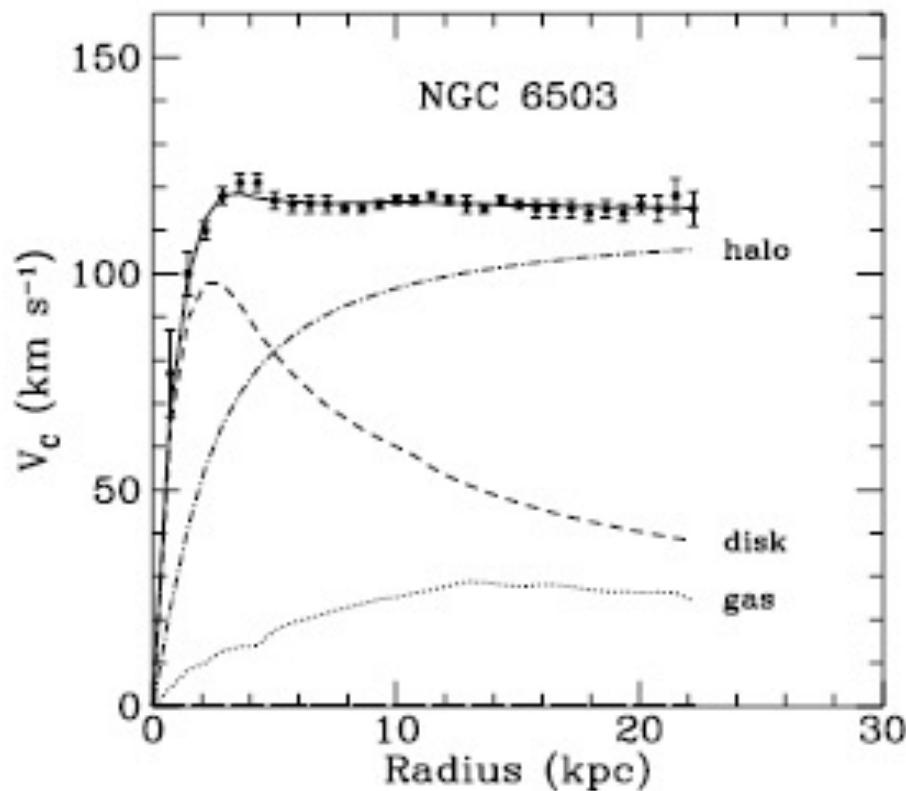

Dmitry Semikoz  
*APC (Paris)*

# Overview:

- Introduction: Dark Matter measurements
- Heavy neutral leptons
- Axion Like Particles (ALPs)
- Weakly Interacting Massive Particles (WIMPs)
- Positron and anti-protons excess in cosmic rays
- Super Heavy Dark Matter (SHDM)
- Conclusions
  
- Seminar: gamma-ray optical depth

# Dark Matter measurements

## • Rotation Curves of galaxies

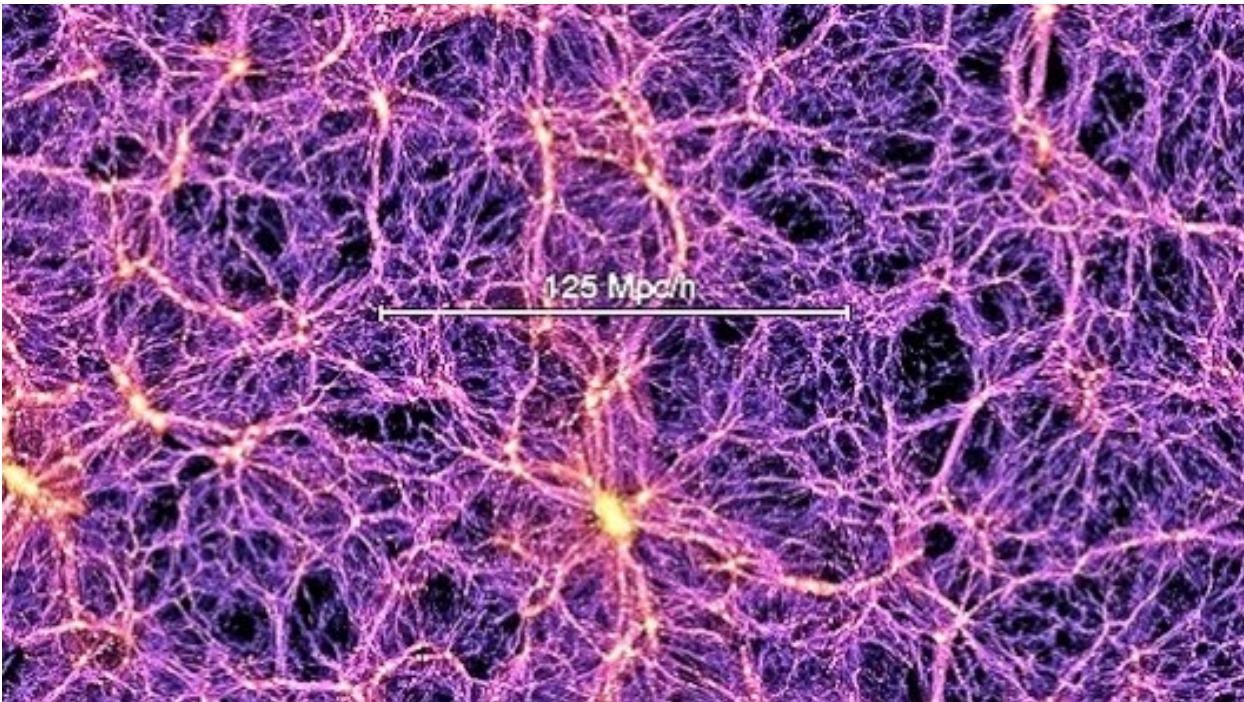

# Clusters of Galaxies

- Red Region: X Ray
- Blue Region:  
*Gravitational lensing*

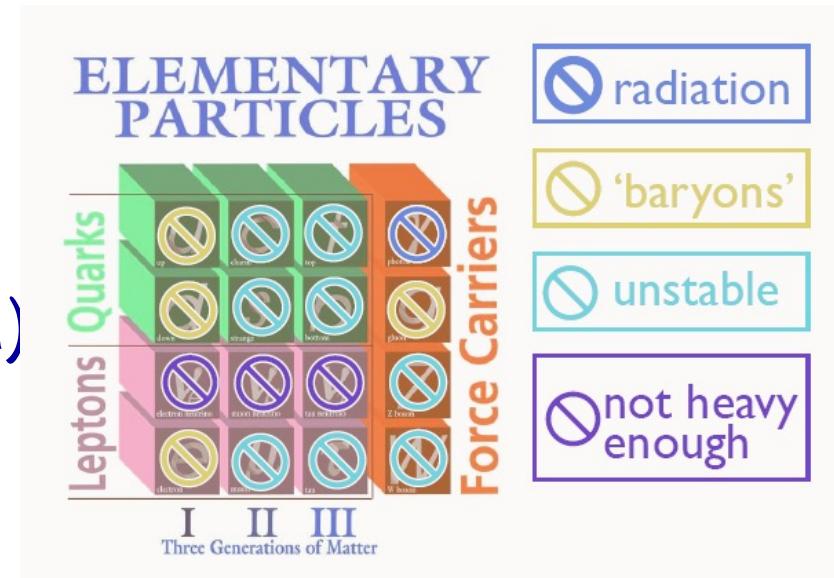

- Large Scale Structure

The N-body  
Simulation of Dark  
Matter Universe  
Structure: Core,  
Filament and  
Cosmic Void.

# • What we know about DM particles so far ?

- neutral
- cold (part of it can be warm)

- weak interaction (with itself and with ordinary matter) ? Maybe!
- profile (around us  $\rho_\chi \approx 0.3 \text{ GeV/cm}^3$   $V \approx 220 \text{ km/s}$ )

# Neutrino dark matter

Neutrino seems to be a perfect dark matter candidate: neutral, stable, massive, abundantly produced in the early Universe

## Cosmic neutrinos

- We know how neutrinos interact and we can compute their primordial number density  $n_\nu = 112 \text{ cm}^{-3}$  (per flavour)
- To give correct dark matter abundance the sum of neutrino masses,  $\sum m_\nu$ , should be  $\sum m_\nu \sim 11 \text{ eV}$

## Tremaine-Gunn bound (1979)

- Such light neutrinos **cannot form small galaxies** – one would have to put too many of them and violated Pauli exclusion principle
- Minimal mass for fermion dark matter  $\sim 300 - 400 \text{ eV}$
- If particles with such mass were **weakly interacting** (like neutrino) – they would overclose the Universe ( $\Omega \sim 3!$ )

# Two roads from neutrino dark matter

Dark matter cannot be **light** and **weakly interacting** at the same time

## Alternatives:

Light and necessarily **super-weakly** interacting — **HNL**

Heavy and weakly interacting — **WIMP**

...and of course other, completely orthogonal ideas, like axions

### HNLs as dark matter

- **Can be light** (down to Tremaine-Gunn bound)
- **Can be warm** (born relativistic and cool down later)
- **Can be decaying** (stability is not required)
- **Can be produced** in correct amounts (via mixing with neutrinos)

# Heavy neutral leptons

## Extension of Standard Model with heavy neutral leptons

Asaka & Shaposhnikov'05. Review: Boyarsky+'09

| The Standard Model of particle physics identifies six generations of fermions. The first generation consists of the up-type quarks u, c, t and the down-type quarks d, s, b. The second generation consists of the electron neutrino $\nu_e$ , muon neutrino $\nu_\mu$ , tau neutrino $\nu_\tau$ and the electron e, muon $\mu$ , tau $\tau$ . The third generation consists of the anti-neutrinos $\bar{\nu}_e$ , $\bar{\nu}_\mu$ , $\bar{\nu}_\tau$ and the anti-leptons $\bar{e}$ , $\bar{\mu}$ , $\bar{\tau}$ .   |      |            |            |                   |                   |      |     |          |         |                  |      |     |           |           |               |      |      |         |         |                  |      |      |          |            |              |      |      |         |         |                  |      |    |           |   |          |      |    |           |       |      |      |    |           |        |     |  |  |  |  |

Can this be a **unified Standard Model** of particle physics and cosmology

Sharing success of the Standard Model at accelerators and resolving major BSM problems:  
Neutrino masses and oscillations; Baryon asymmetry of the Universe; Dark matter

# Type I seesaw model

$$\mathcal{L}_{\text{Seesaw Type I}} = \mathcal{L}_{\text{SM}} + i\bar{N}\partial N + Y \bar{N}(\tilde{H} \cdot L) + \frac{1}{2} \bar{N}MN^c + \text{h.c.}$$

Majorana mass term

Dirac mass term

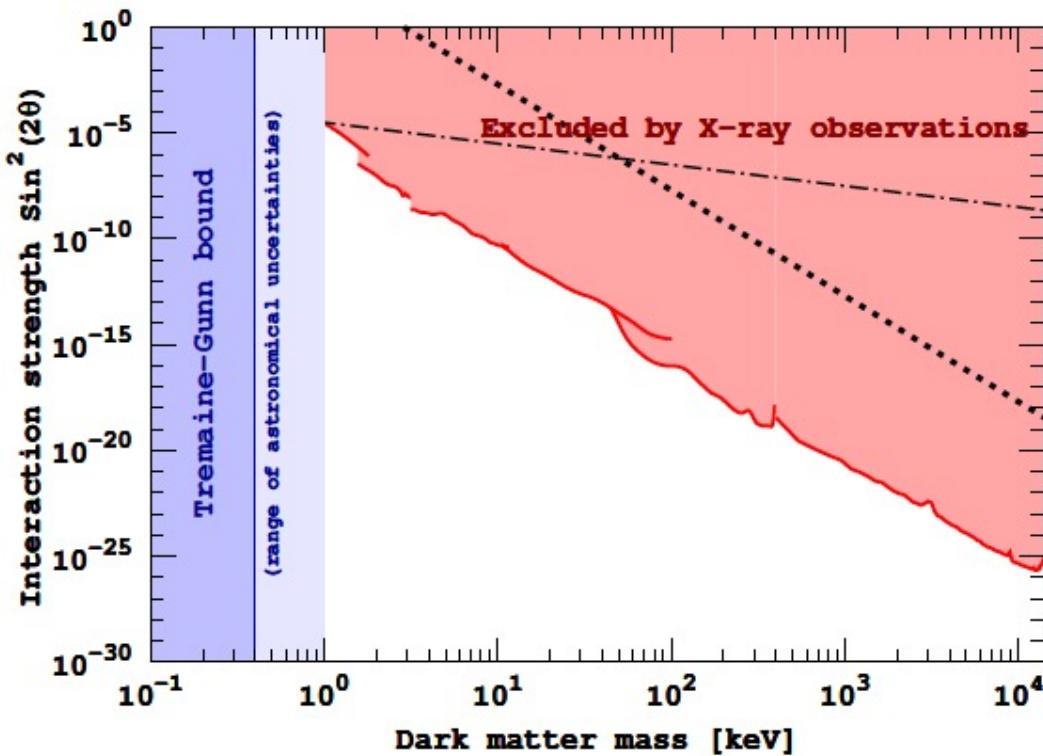

- Neutrinos are light because  $m_{\text{Dirac}} \ll M$ :
- active-sterile mixing angle

$$m_\nu \simeq \frac{(m_{\text{Dirac}})^2}{M} = U^2 M$$

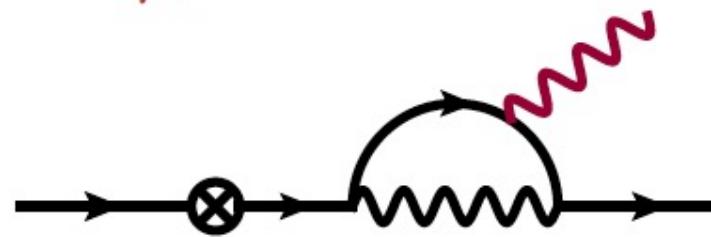

$$U = \frac{m_{\text{Dirac}}}{M} \ll 1$$

The new particle is called “Sterile neutrino” or “heavy neutral lepton” or **HNL**

# Parameter space of HNL dark matter I

- Non-observation of decay line  $N \rightarrow \gamma + \nu$

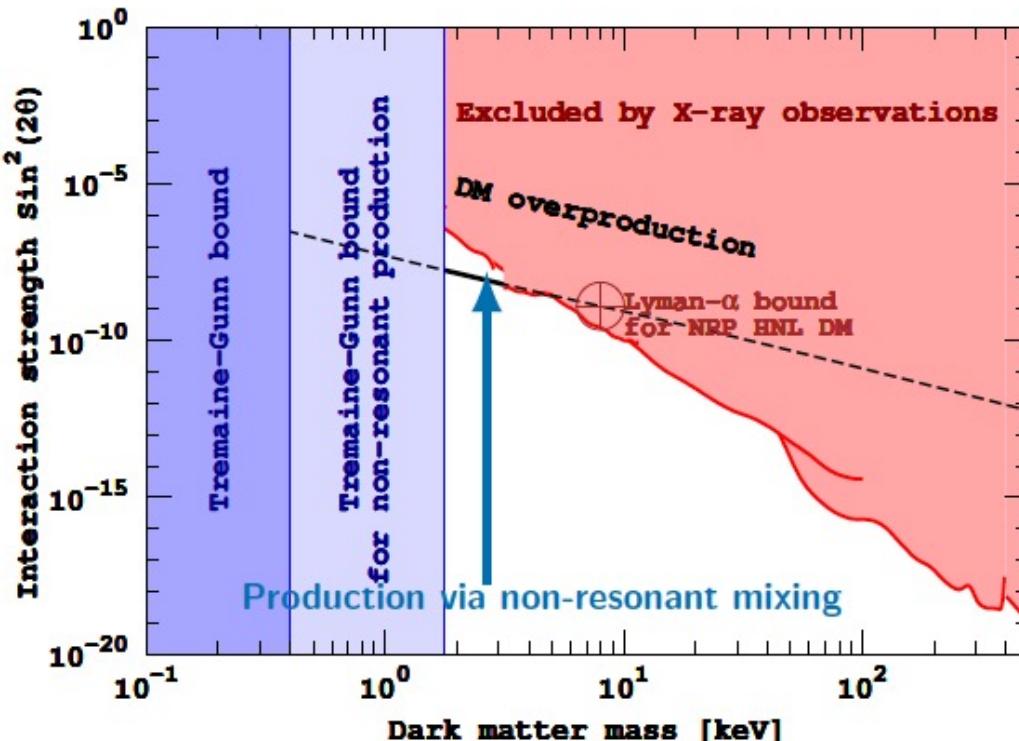

- Lifetime  $\gg$  Age of the Universe (dotted line)
- Contribution to neutrino masses

$$m_{\odot} \sim U^2 M$$

[Asaka+'05; Boyarsky+'06]

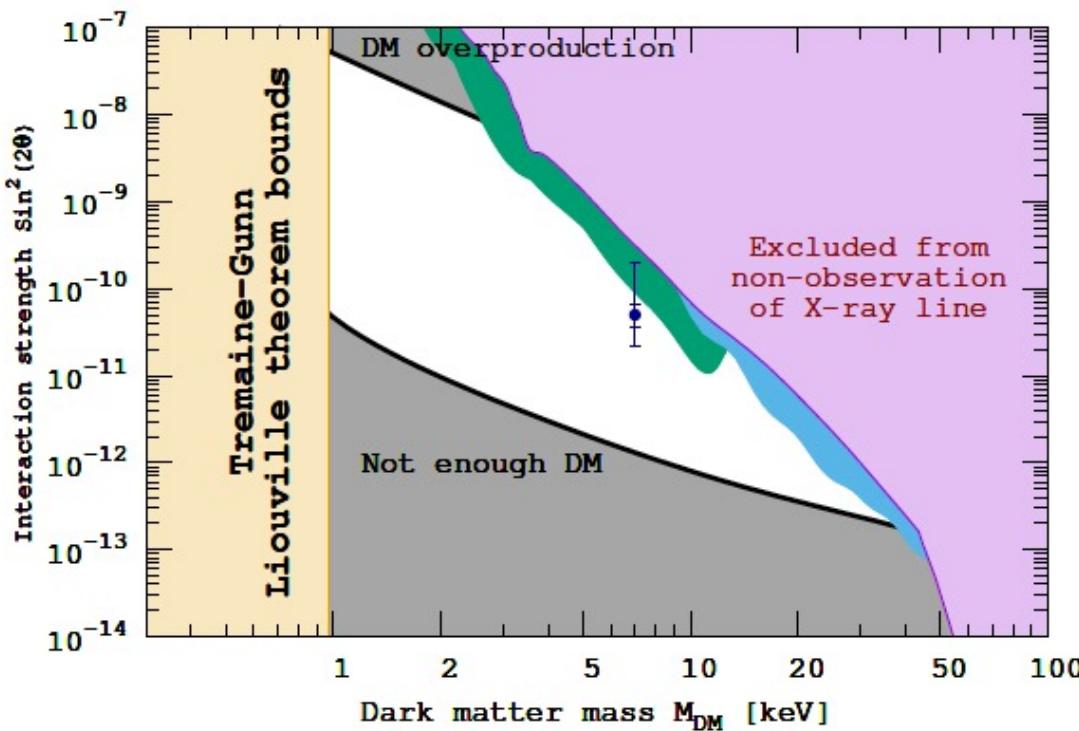

# Parameter space of HNL dark matter II

- Production via non-resonant mixing  
[Dodelson & Widrow'93; Asaka, Laine, Shaposhnikov'06]
- Liouville bound (neglecting feedback from baryons)  
[Boyarsky, O.R. et al.'08;  
Gorbunov+'08]
- Lyman- $\alpha$  bound  
[Boyarsky, Lesgourges, O.R., Viel'08]

- Production via mixing and decay signal depend on the same mixing angle  $U^2$
- X-ray bounds grow very fast with mass (flux  $\sim M_N^5$ )

# Parameter space of HNL dark matter III

- White region: production via **resonant** mixing  
[Shi & Fuller'93; Laine & Shaposhnikov'08]
- Requires: lepton asymmetry exceeding  $\eta_{baryon}$  by many orders of magnitude at  $T \sim 100 - 500 \text{ MeV}$

## In summary

- HNL DM is **light** ( $1 - 50$  keV) if there are no other particles
- Yukawa of HNL DM are tiny ( $\mathcal{O}(10^{-10})$  or below)

# Reminder: 3.5 keV line story

Two groups reported an identified feature in the X-ray spectra of dark matter-dominated objects

## DETECTION OF AN UNIDENTIFIED EMISSION LINE IN THE STACKED X-RAY SPECTRUM OF GALAXY CLUSTERS

PRL (2014) [1402.4119]

- **Energy:** 3.5 keV. Statistical error for line position  $\sim 30 - 50$  eV.
- **Lifetime:**  $\sim 10^{28}$  sec (uncertainty: factor  $\sim 3$ )
- **Possible origin:** decay  $DM \rightarrow \gamma + \nu$  (fermion) or  $DM \rightarrow \gamma + \gamma$  (boson)

# Subsequent works

For overview see e.g. [1602.04816] “A White Paper on keV Sterile Neutrino Dark Matter”

- Subsequent works confirmed the presence of the 3.5 keV line in some of the objects  
[Boyarsky O.R.+](#); [Iakubovskyi+](#); [Franse+](#); [Bulbul+](#); [Urban+](#); [Cappelluti+](#)
- challenged its existence in other objects  
[Malyshov+](#); [Anderson+](#); [Tamura+](#); [Sekiya+](#)
- argued astrophysical origin of the line  
[Gu+](#); [Carlson+](#); [Jeltema & Profumo](#); [Riemer-Sørensen](#); [Phillips+](#)

[1507.06655]

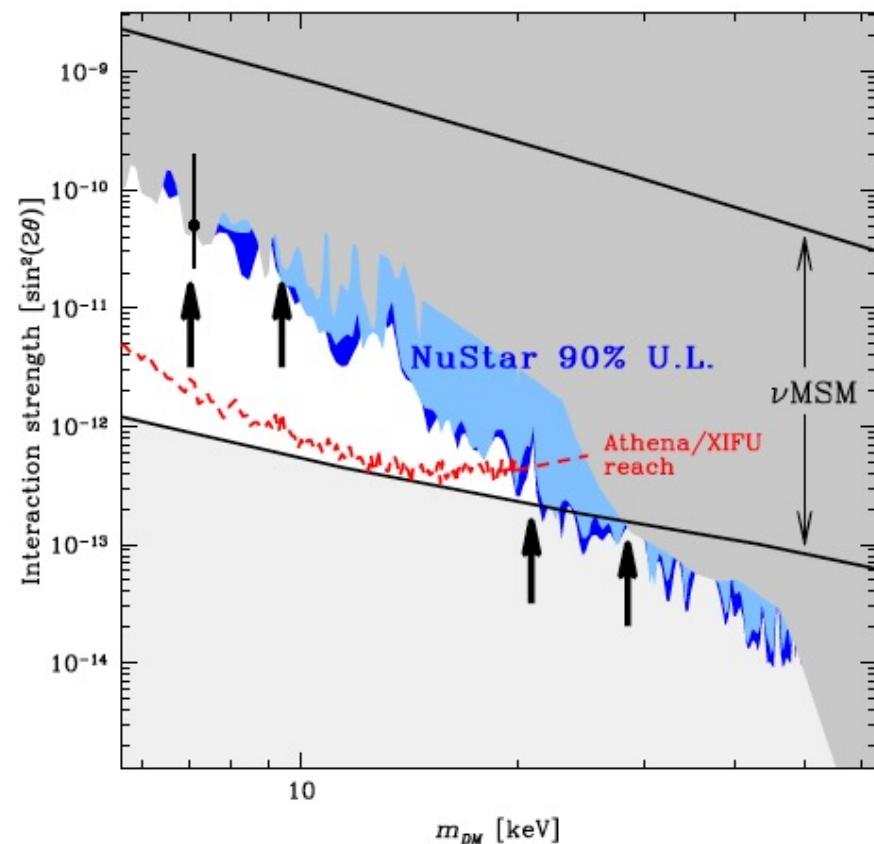

**A common explanation for every detection and non-detection?**

- When comparing bounds from different objects one should be careful — dark matter content in each of them uncertain by a factor 2–3

# Line in NuStar

Milky Way halo. Neronov & Malyshev [1607.07328]. Also Ng+ [1609.00667]

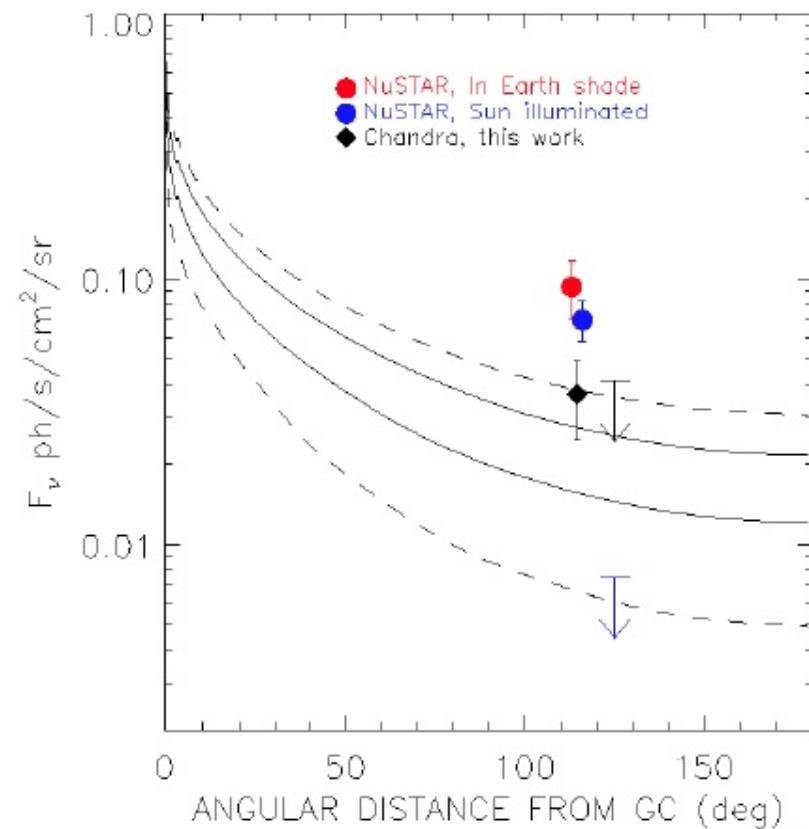

- The 3.5 keV is present in the spectrum with  $11\sigma$  significance
- The spectrum of NuStar ends at 3 keV, so this is a lower edge of sensitivity band
- The 3.5 keV line has been previously attributed to reflection of the sunlight on the telescope structure
- However, in the dataset when Earth shields satellite from the Sun the line is present with the same flux

# Line in Chandra

Cappelluti+ '17

- Most recently: 10 Msec of Chandra observation of Chandra Deep Fields
- $3\sigma$  detection of a line at  $\sim 3.5$  keV
- If interpreted as dark matter decay – this is a signal from Galactic halo outskirts ( $\sim 115^\circ$  off center)
- Chandra has mirrors made of Iridium (rather than Gold as XMM or Suzaku) – absorption edge origin becomes unlikely

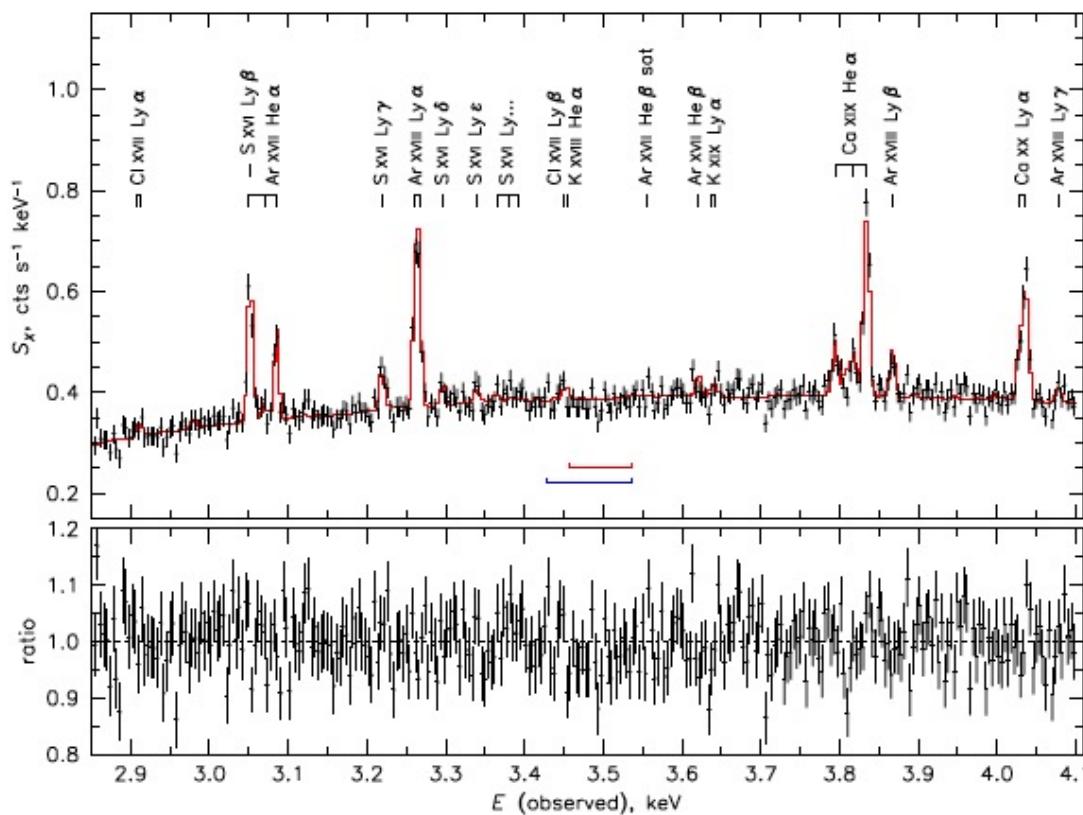

By now the 3.5 keV line has been observed with 4 existing X-ray telescopes, making the systematic (calibration uncertainty) origin of the line highly unlikely

# Next step for 3.5 keV line: resolve the line

- Astro-H/Hitomi – new generation X-ray spectrometer with a superb spectral resolution
- Launched February 17, 2016
- ☹ Lost few weeks later
- Before its failure observed the center of Perseus galaxy cluster
- The observations was in calibration phase (additional filters block most of X-ray below 3 keV)

Perseus center spectrum [1607.07420]

# What did we learn with existing Hitomi data?

- Due to its super energy resolution, *Hitomi* can distinguish between atomic line broadening (thermal velocities  $\sim 10^2$  km/sec) and decaying dark matter line broadening (virial velocity  $\sim 10^3$  km/sec)
- Even the short observation of Hitomi showed that Potassium, Chlorine, etc. do not have super-solar abundance in Perseus cluster  $\Rightarrow$  3.5 keV line is **not** astrophysical
- Bounds much weaker for a **broad** (dark matter) line  $\Rightarrow$  not at tension with previous detections

- This does not seem to be astrophysics (Hitomi spectrum)
- This does not seem to be systematics (4 different instruments)
- ???

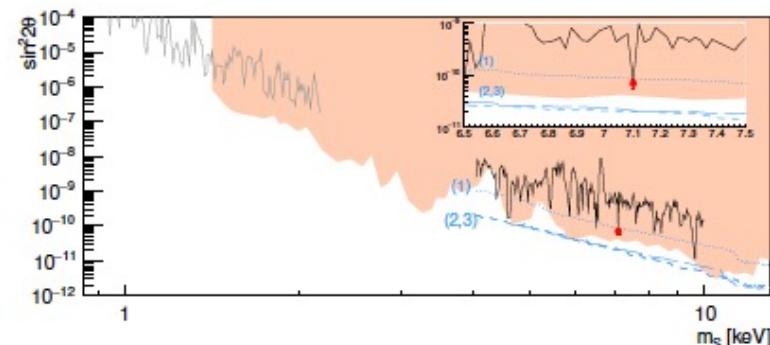

# Future of decaying dark matter searches in X-rays

## Another Hitomi

JAXA is planning to send a replica of Hitomi satellite (within about 2 years)

## Microcalorimeter on sounding rocket (2017)

- Large field-of-view and very high spectral resolution
- Can resolve narrow lines from diffuse sources
- Flying time  $\sim 10^2$  sec

## Athena+

- Large ESA X-ray mission (2028) with X-ray spectrometer (X-IFU)
- Very large collecting area ( $10\times$  that of XMM)

# ALPs

# Physics case for axions: Strong CP problem

- > Most general gauge invariant Lagrangian of QCD up to dimension four:

$$\mathcal{L} = -\frac{1}{4}G_{\mu\nu}^a G^{a,\mu\nu} + \bar{q}(i\gamma_\mu D^\mu - \mathcal{M}_q) q - \frac{\alpha_s}{8\pi}\theta G_{\mu\nu}^a \tilde{G}^{a,\mu\nu}$$

- Fundamental parameters of QCD: strong coupling  $\alpha_s$ , quark masses  $m_u, m_d, \dots$ , and theta parameter

$$\bar{\theta} = \theta + \arg \det \mathcal{M}_q$$

- > Theta term  $\propto G_{\mu\nu}^a \tilde{G}^{a,\mu\nu} \propto \mathbf{E}^a \cdot \mathbf{B}^a$  odd under P and T, i.e. leads to CP violation in flavor conserving interactions
- > Most sensitive probe of P and T violation in flavor conserving interactions: electric dipole moment (EDM) of neutron; experimentally

$$|d_n| < 2.9 \times 10^{-26} \text{ e cm}$$

- > Strong CP problem:

$$d_n(\bar{\theta}) \sim \frac{e\bar{\theta}m_u m_d}{(m_u + m_d)m_n^2} \sim 6 \times 10^{-17} \bar{\theta} \text{ e cm} \Rightarrow |\bar{\theta}| \lesssim 10^{-9}$$

# Physics case for axions: Strong CP problem

- > Peccei-Quinn solution of strong CP problem based on observation that the vacuum energy in QCD, inferred from effective chiral Lagrangian,

$$V(\bar{\theta}) = \frac{m_\pi^2 f_\pi^2}{2} \frac{m_u m_d}{(m_u + m_d)^2} \bar{\theta}^2 + \mathcal{O}(\bar{\theta}^4)$$

has localised minimum at vanishing theta parameter:

If theta were a dynamical field, its vacuum expectation value (vev) would dynamically relax to zero

- > Introduce field  $a(x)$  as dynamical theta parameter, enjoying a shift symmetry,  $a \rightarrow a + \text{const.}$ , broken only by anomalous couplings to gauge fields,

$$\mathcal{L} \supset \frac{1}{2} \partial_\mu a \partial^\mu a - \frac{\alpha_s}{8\pi} \left( \bar{\theta} + \frac{a}{f_a} \right) G_{\mu\nu}^b \tilde{G}^{b,\mu\nu} - \frac{\alpha}{8\pi} C_{a\gamma} \frac{a}{f_a} F_{\mu\nu} \tilde{F}^{\mu\nu} + \dots$$

- Can eliminate theta by shift  $a(x) \rightarrow \bar{a}(x) \equiv a(x) + \bar{\theta} f_a$ ; QCD dynamics (see above) leads to vanishing vev,  $\langle \bar{a} \rangle = 0$ , i.e. P, T, and CP conserved
- Elementary particle excitation of field around vev: **axion** (Weinberg 78; Wilczek 78)

# Physics case for axions: Strong CP problem

$$\mathcal{L} \supset \frac{1}{2} \partial_\mu a \partial^\mu a - \frac{\alpha_s}{8\pi} \left( \bar{\theta} + \frac{a}{f_a} \right) G_{\mu\nu}^b \tilde{G}^{b,\mu\nu} - \frac{\alpha}{8\pi} C_{a\gamma} \frac{a}{f_a} F_{\mu\nu} \tilde{F}^{\mu\nu} + \dots$$

- > For large decay constant  $f_a$ : prime paradigm of a WISP  
 (Kim 79; Shifman et al 80; Zhitnitsky 80; Dine et al 81)

$$g_{a\gamma} = \frac{\alpha}{2\pi f_a} \left( C_{a\gamma} - \frac{2}{3} \frac{m_u + 4m_d}{m_u + m_d} \right) \sim 10^{-12} \text{ GeV}^{-1} \left( \frac{10^9 \text{ GeV}}{f_a} \right)$$

$$m_a = \frac{m_\pi f_\pi}{f_a} \frac{\sqrt{m_u m_d}}{m_u + m_d} \simeq 6 \text{ meV} \times \left( \frac{10^9 \text{ GeV}}{f_a} \right)$$

- > Strong constraints from astrophysics (non-excessive energy loss of stars):

$$f_a \gtrsim 10^9 \text{ GeV}$$

# Physics case for axions and ALPs: NGBs of SSB

- In 4D field theoretic extensions of the Standard Model (SM), axion field realised as phase of a complex  $SU(2)_L \times U(1)_Y$  singlet scalar field whose vev breaks a global anomalous chiral  $U(1)_{\text{PQ}}$  symmetry,

$$\Phi(x) = \frac{v_{\text{PQ}} + \rho(x)}{\sqrt{2}} e^{ia(x)/f_a}$$

- At energies much below the symmetry breaking scale  $v_{\text{PQ}}$  the low-energy effective field theory is that of a (pseudo-)Nambu-Goldstone Boson (NGB) with decay constant

$$f_a = v_{\text{PQ}}/C_{ag}$$

- More axion-like particles (ALPs) may arise as NGBs from the breaking of more than one anomalous  $U(1)_{\text{PQ}}$

$$\mathcal{L} = \frac{1}{2} \partial_\mu a_i \partial^\mu a_i - \frac{\alpha_s}{8\pi} \left( \bar{\theta} + C_{ig} \frac{a_i}{f_{a_i}} \right) G_{\mu\nu}^b \tilde{G}^{b,\mu\nu} - \frac{\alpha}{8\pi} C_{i\gamma} \frac{a_i}{f_{a_i}} F_{\mu\nu} \tilde{F}^{\mu\nu} + \dots$$

# Photon/axion conversions

- Axions proposed as a by-product of the Peccei-Quinn solution of the strong-CP problem.
- Axion-like particle (ALP): mass and coupling not related.
- Can be suitable dark matter candidates.
- Expected to convert into photons (and vice-versa) in the presence of magnetic fields.

Probability of conversion (e.g. Raffelt & Stodolsky 88, Mirizzi+07):

$$P_0 = (\Delta_B s)^2 \frac{\sin^2(\Delta_{\text{osc}} s/2)}{(\Delta_{\text{osc}} s/2)^2} \quad \text{with} \quad \left\{ \begin{array}{l} \Delta_B = \frac{B_t}{2M} \simeq 1.7 \times 10^{-21} M_{11} B_{\text{mG}} \text{ cm}^{-1}, \\ \Delta_{\text{osc}}^2 \simeq (\Delta_{\text{CM}} + \Delta_{\text{pl}} - \Delta_a)^2 + 4\Delta_B^2, \end{array} \right.$$

Photon/axion conversions the main vehicle used in axion searches at present (ADMX, CAST...).

Some astrophysical environments  
fulfill the mixing requirements

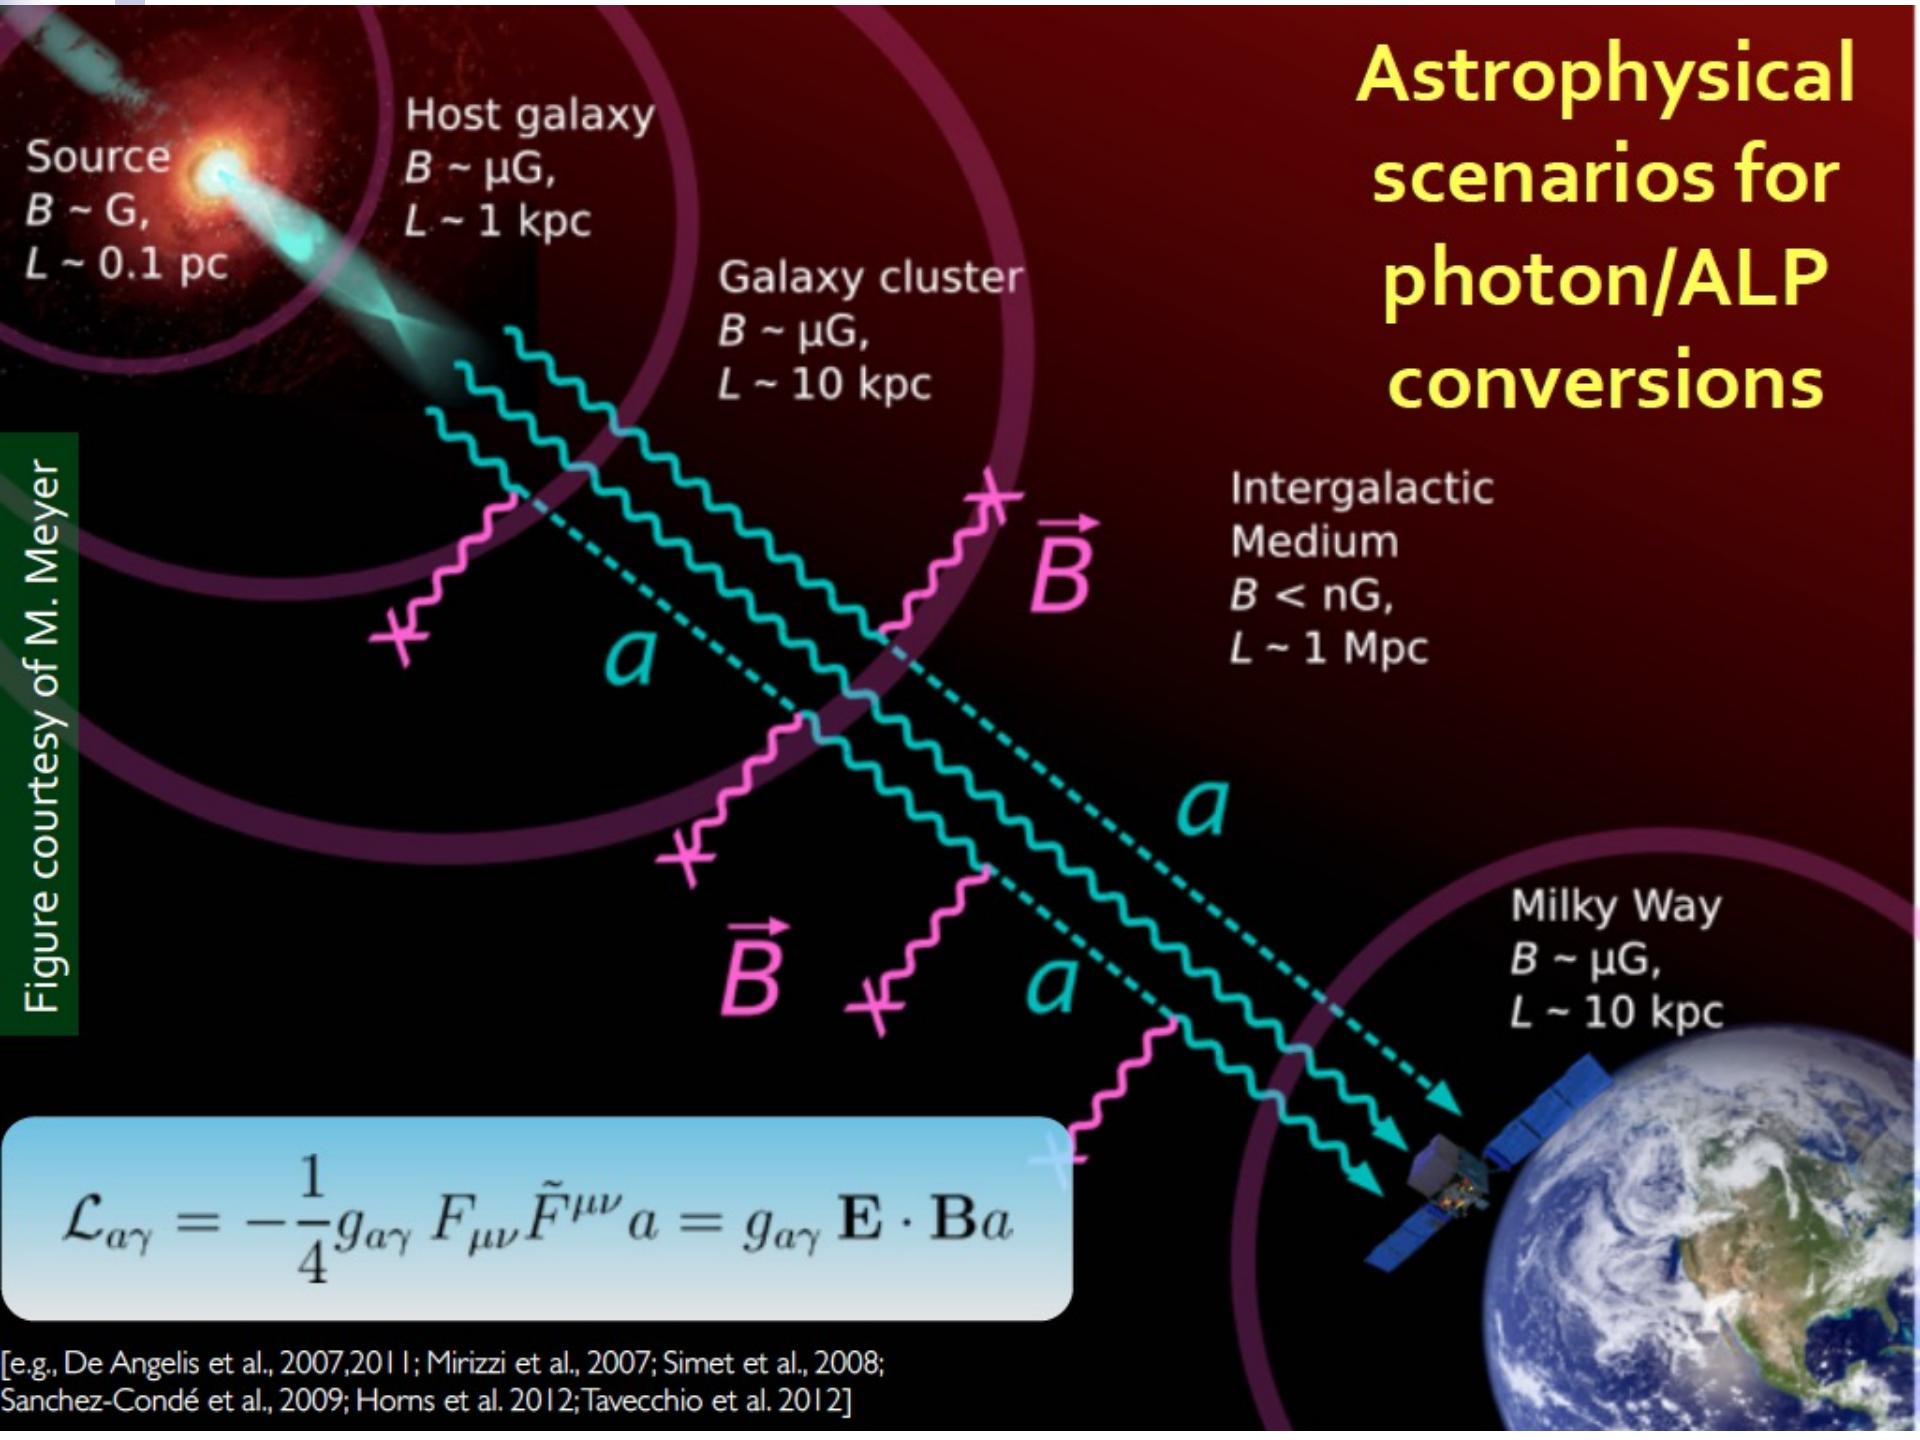

$$\frac{15 \cdot B_G \cdot s_{pc}}{M_{11}} \geq 1$$

$M_{11} \geq 0.114 \text{ GeV}$  (CAST limit)

$M_{11}$ : coupling constant inverse ( $g_{ag}/10^{11} \text{ GeV}$ )  
 $B_G$ : magnetic field (G)  
 $s_{pc}$ : size region (pc)

# Astrophysical scenarios for photon/ALP conversions

Figure courtesy of M. Meyer

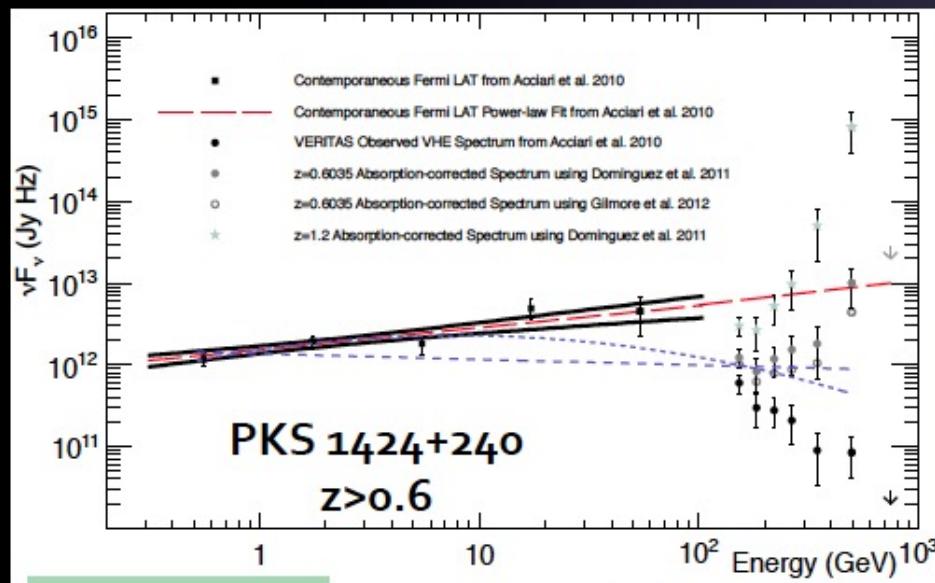

$$\mathcal{L}_{a\gamma} = -\frac{1}{4}g_{a\gamma} F_{\mu\nu}\tilde{F}^{\mu\nu}a = g_{a\gamma} \mathbf{E} \cdot \mathbf{B}a$$

# WIMPs

## Basic Concepts

A. dark matter particles could interact with standard model particles and reach thermal equilibrium. Non-thermal processes are also OK.

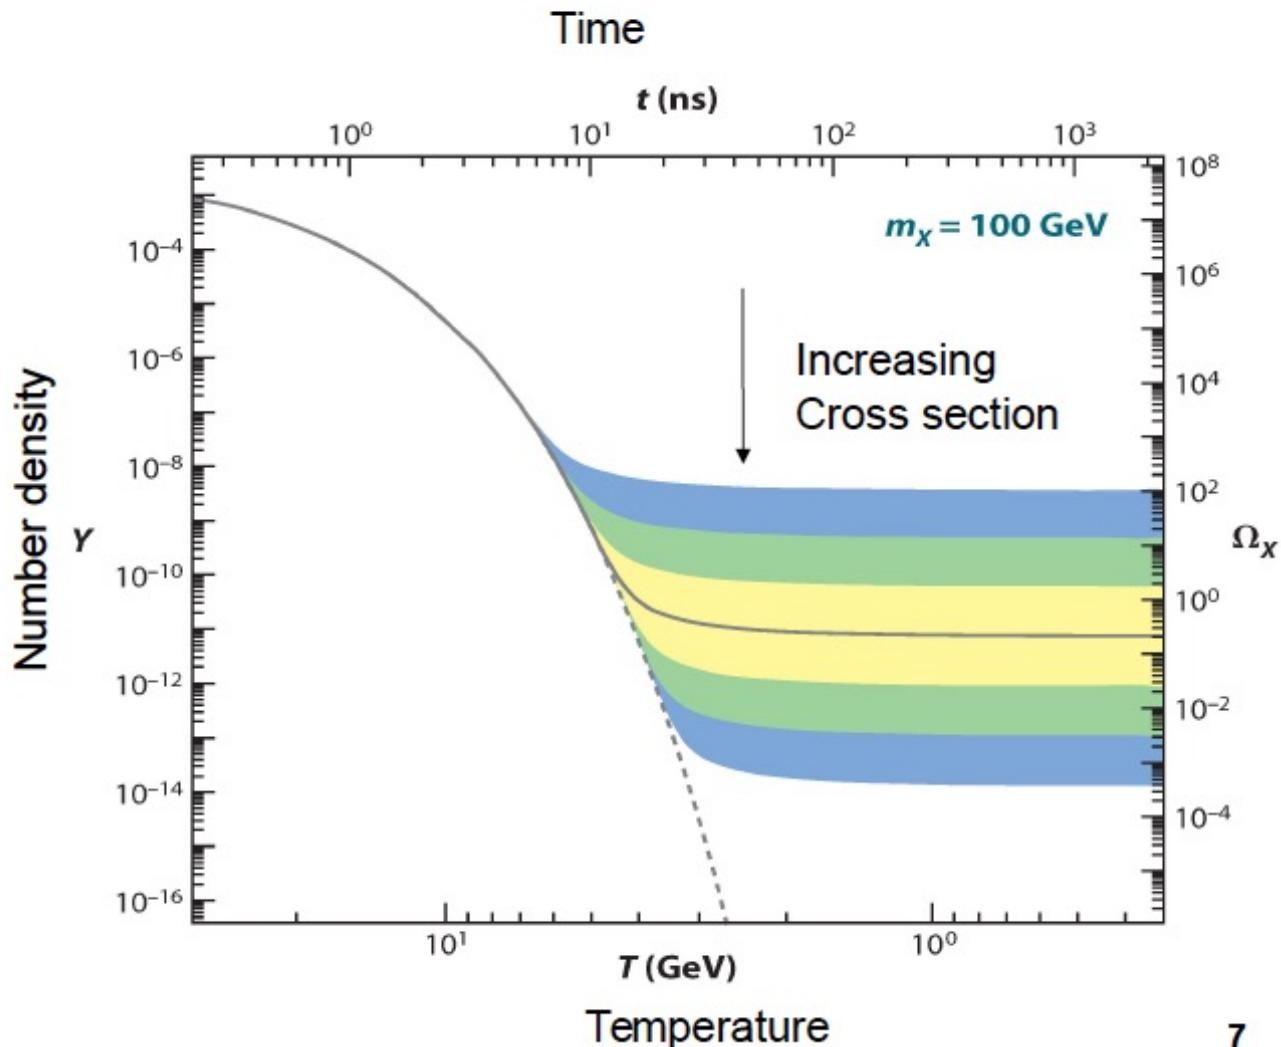

B. After the universe cooled down and expanded, eventually the expansion rate equaled the interaction rate → freeze-out.

C. After the freeze-out the dark matter particles clustered forming the structures we observe today.

D. In the WIMP paradigm the abundance is connected to the annihilation cross section at freeze-out.

## Dark Matter Abundance (WIMP)

Right relic abundance → Annihilation cross section at the weak scale

We study the gamma rays observed by the Fermi Gamma Ray Space Telescope from the direction of the Galactic Center and find that their angular distribution and energy spectrum are well described by a dark matter annihilation scenario. In particular, we find a good fit to the data for dark matter particles with a 25-30 GeV mass, an annihilation cross section of  $\sim 9 \times 10^{-26} \text{ cm}^3/\text{s}$ , and that are distributed with a cusped halo profile,  $\rho(r) \propto r^{-1.1}$ , within the inner kiloparsec of the Galaxy. We cannot however exclude the possibility that these photons originate from an astrophysical source.

### Indirect Search for Dark Matter from the center of the Milky Way with the Fermi-Large Area Telescope

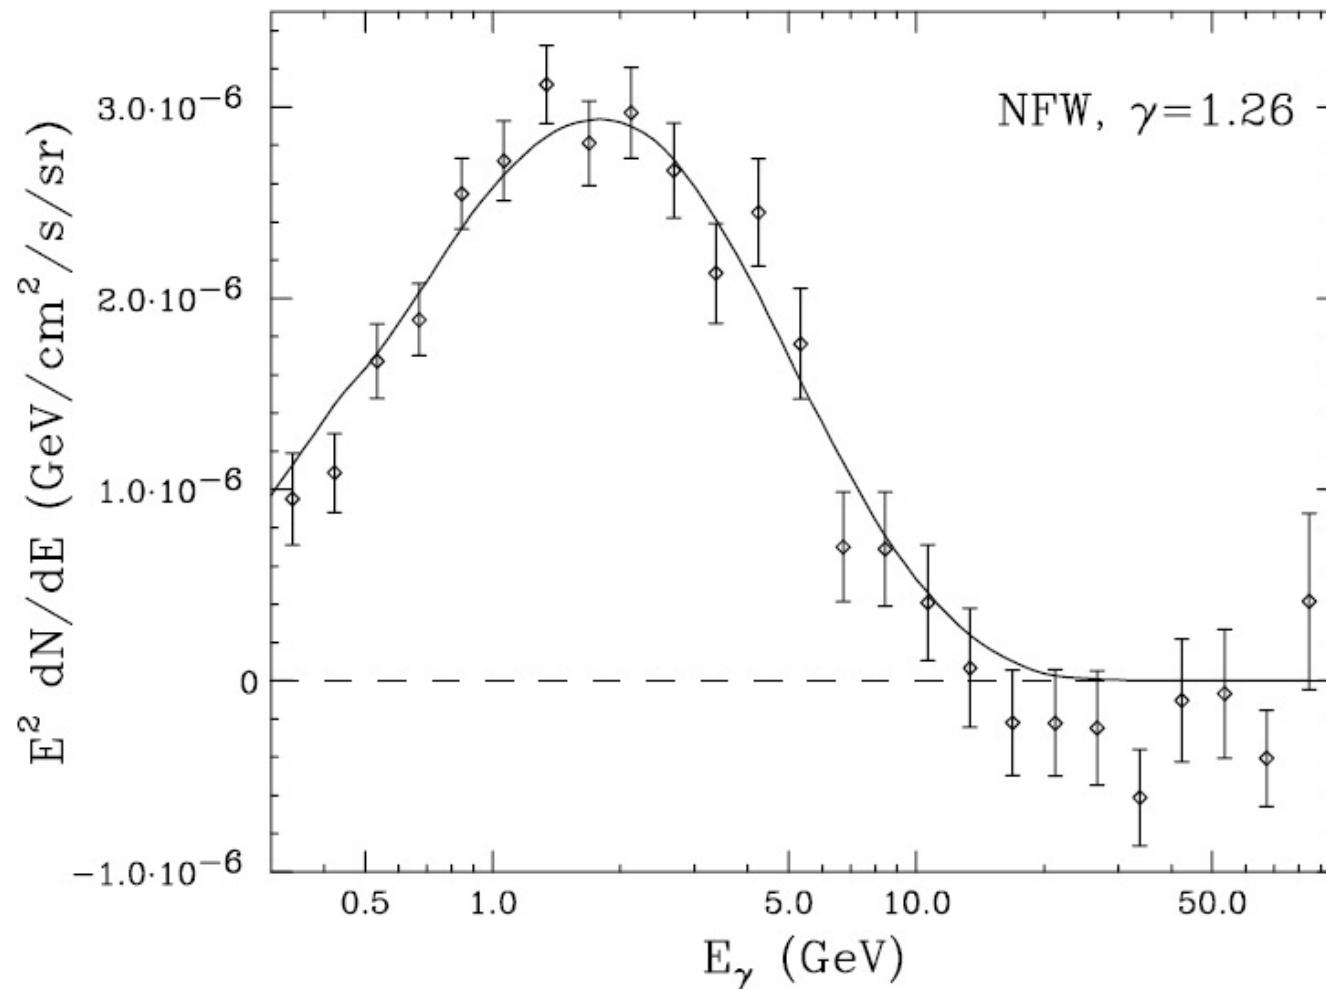

Vincenzo Vitale and Aldo Morselli, for the Fermi/LAT Collaboration  
Istituto Nazionale di Fisica Nucleare, Sez. Roma Tor Vergata, Roma, Italy

Today, a simple model of the Galactic diffuse emission, as we know today, can account for the large majority of the detected gamma-ray emission from the Galactic Center. Nevertheless a residual emission is left, not accounted for by the above models.

An improved model of the Galactic diffuse emission and a careful evaluation of new (possibly unresolved) sources (or source populations) will improve the sensitivity for a DM search.

## Abstract

We conjecture that the highest energy cosmic rays,  $E > E_{GZK}$ , where  $E_{GZK} \sim 5 \cdot 10^{19}$  eV is the Greisen–Zatsepin–Kuzmin cut-off energy of cosmic ray spectrum, may provide a unique window into the very early epoch of the Universe, namely, that of reheating after inflation, provided these cosmic rays are due to decays of parent superheavy long-living  $X$ -particles.

These particles may constitute a considerable fraction of cold dark matter in the Universe. We argue that the unconventionally long lifetime of the superheavy particles, which should be in the range of  $10^{10} – 10^{22}$  years, might require novel particle physics mechanisms of their decays, such as instantons. We propose a toy model illustrating the instanton scenario.

## Abstract

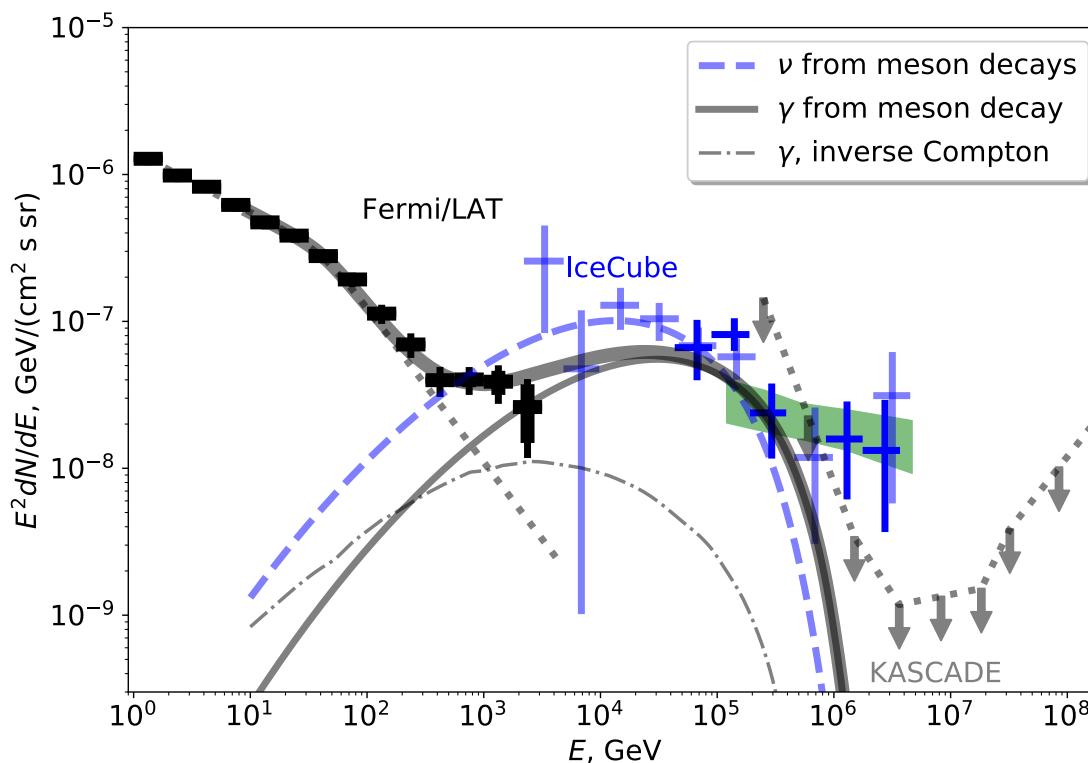

The highest energy cosmic rays, above the Greisen–Zatsepin–Kuzmin cut-off of cosmic ray spectrum, may be produced in decays of superheavy long-living  $X$ -particles. We conjecture that these particles may be produced *naturally* in the early Universe from *vacuum fluctuations* during inflation and may constitute a considerable fraction of Cold Dark Matter. We predict a new cut-off in the UHE cosmic ray spectrum  $E_{\text{cut-off}} < m_{\text{inflaton}} \approx 10^{13}$  GeV, the exact position of the cut-off and the shape of the cosmic ray spectrum beyond the GZK cut-off being determined by the QCD quark/gluon fragmentation. The Pierre Auger Project installation might discover this phenomenon.
