INTRODUCTION: history of Gravitational Wave searches

General Relativity

1915: Einstein's Theory of General Relativity

1916: Einstein paper on linear approximation to general relativity with multiple applications, including gravitational waves.

688 Sitzung der physikalisch-mathematischen Klasse vom 22. Juni 1916

Näherungsweise Integration der Feldgleichungen
der Gravitation.

VON A. EINSTEIN.

Gravitational waves

$$A = \frac{\kappa}{24\pi} \sum_{\alpha\beta} \left(\frac{\partial^3 J_{\alpha\beta}}{\partial t^3} \right)^2. \quad (21)$$

Würde man die Zeit in Sekunden, die Energie in Erg messen, so würde zu diesem Ausdruck der Zahlenfaktor $\frac{1}{c^4}$ hinzutreten. Berücksichtigt man außerdem, daß $\kappa = 1.87 \cdot 10^{-27}$, so sieht man, daß A in allen nur denkbaren Fällen einen praktisch verschwindenden Wert haben muß.

“... in all conceivable cases, **A** must have a practically vanishing value.”

Gravitational waves are predicted by Einstein, but he recognizes that they are too small.

Gravitational waves

154 Gesamtsitzung vom 14. Februar 1918. — Mitteilung vom 31. Januar

Über Gravitationswellen.

Von A. EINSTEIN.

On Gravitational Waves – 1918

Einstein works out the remaining details on gravitational waves: emission (quadrupole), polarizations, they carry energy, etc

Dabei ist zur Abkürzung

$$\mathfrak{J}_{\mu\nu} = \int x_\mu x_\nu \rho dV_o. \quad (23)$$

gesetzt; $\mathfrak{J}_{\mu\nu}$ sind die Komponenten des (zeitlich variablen) Trägheitsmomentes des materiellen Systems.

$$\gamma'_{23} = -\frac{z}{4\pi R} \ddot{\mathfrak{J}}_{23}.$$

Are Gravitational Waves Real?

Continued debate on whether gravitational waves really exist up until 1957 Chapel Hill conference.

Felix Pirani paper and presentation: relative acceleration of particle pairs can be associated with the Riemann tensor. The interpretation of the attendees was that non-zero components of the Riemann tensor were due to gravitational waves.

Sticky bead (Felix Pirani, Richard Feynman, Hermann Bondi)

Joe Weber of the University of Maryland, and from this inspiration started to think about gravitational wave detection.

What Are Gravitational Waves?

- General relativity (1916) prediction.
- Gravity is not really a force in GR, but a space-time deformation.
- Masses locally deform space-time.
- Accelerated masses emit gravitational waves, ripples in space time.
- Space-time is rigid:

The amplitude of the deformation is tiny.

Need cataclysmic events in order to

expect to measure something on Earth ... $h \sim 10^{-21}$

- Gravitational Wave sources: mainly astrophysical in the 10 Hz -10 kHz bandwidth

Binary Pulsar PSR 1913+16

$M_1 = 1.438 M_{\odot}$
 $M_2 = 1.390 M_{\odot}$
8 hour orbit
Orbit decays by
3mm per orbit.

Discovered in
1974 by Russell
Hulse and
Joseph Taylor,
then at
University
Massachusetts.

A Nobel Prize for ...

“... for the discovery of a new type of pulsar, a discovery that has opened up new possibilities for the study of gravitation.”
1993

For more on this Nobel, see, "The Nobel pulsar", Nelson Christensen. *Science*, Vol. 348 no. 6236 p. 766 (2015).

First Proof That Gravitational Waves Exist - 1982

A NEW TEST OF GENERAL RELATIVITY: GRAVITATIONAL RADIATION AND THE BINARY PULSAR PSR 1913+16

J. H. TAYLOR AND J. M. WEISBERG

Department of Physics and Astronomy, University of Massachusetts, Amherst; and Joseph Henry Laboratories,
Physics Department, Princeton University

Received 1981 July 2; accepted 1981 August 28

ABSTRACT

Observations of pulse arrival times from the binary pulsar PSR 1913+16 between 1974 September and 1981 March are now sufficient to yield a solution for the component masses and the absolute size of the orbit. We find the total mass to be almost equally distributed between the pulsar and its unseen companion, with $m_p = 1.42 \pm 0.06 M_\odot$ and $m_c = 1.41 \pm 0.06 M_\odot$. These values are used, together with the well determined orbital period and eccentricity, to calculate the rate at which the orbital period should decay as energy is lost from the system via gravitational radiation. According to the general relativistic quadrupole formula, one should expect for the PSR 1913+16 system an orbital period derivative $\dot{P}_b = (-2.403 \pm 0.005) \times 10^{-12}$. Our observations yield the measured value $\dot{P}_b = (-2.30 \pm 0.22) \times 10^{-12}$. The excellent agreement provides compelling evidence for the existence of gravitational radiation, as well as a new and profound confirmation of the general theory of relativity.

RELATIVISTIC MEASUREMENTS FROM TIMING THE BINARY PULSAR PSR B1913+16

J. M. WEISBERG AND Y. HUANG

Department of Physics and Astronomy, Carleton College, Northfield, MN 55057, USA; jweisber@carleton.edu

Received 2016 January 19; revised 2016 April 20; accepted 2016 June 1; published 2016 September 21

“The points, with error bars too small to show, represent our measurements”

Gravitational Wave Detection

Inspired and motivated by the Chapel Hill Conference, Joe Weber of the University of Maryland constructs the first gravitational wave detectors.

"In 1958 I was able to prove, using Einstein's equations that a gravitational wave would change the dimensions of an extended body."

EVIDENCE FOR DISCOVERY OF GRAVITATIONAL RADIATION*

J. Weber

Department of Physics and Astronomy, University of Maryland, College Park, Maryland 20742

(Received 29 April 1969)

Coincidences have been observed on gravitational-radiation detectors over a base line of about 1000 km at Argonne National Laboratory and at the University of Maryland. The probability that all of these coincidences were accidental is incredibly small. Experiments imply that electromagnetic and seismic effects can be ruled out with a high level of confidence. These data are consistent with the conclusion that the detectors are being excited by gravitational radiation.

1960s & 70s: Detection claims and theoretical studies on sources

The future looks promising—but by no means certain! The search for gravitational waves is a game requiring long, hard effort with a definite risk of total failure—but with very great payoff if it succeeds.

K. Thorne 1980

FIG. 3. Estimates of the strengths of the gravitational waves that bathe the Earth. See text for explanation of the lines and hatched regions.

Interferometric GW Detectors

First suggestion: 1962 two Soviet physicists, V.I. Pustovoit and M.E. Gertsenshtein, noted that the use of a Michelson interferometer would be a possible means to detect gravitational waves over a frequency range that was broader than the Weber bars.

1970's, Robert Forward (student of Weber) at Hughes Aircraft Co. used a Michelson interferometer to search for gravitational waves (MIT) and astronaut Philip Chapman (also at MIT) for ins

The wideband interferometer

VII. CALIBRATION OF EAR

When the interferometer was working well, we were able to hear single-frequency 3- to 10-kHz tones of 10-fm rms amplitude introduced into the interferometer by the piezoelectric displacement transducer.

Since the noise level of the interferometer in that band is about $0.9 \text{ fm/Hz}^{1/2}$, this means that the audio system, including our ear-brain combination, had an effective detection bandwidth of about 120 Hz.

Rai Weiss Interferometer Study

1972: Weiss produces the first detailed study for a realistic interferometric gravitational wave detector.

Systematically addresses a number of realistic noise sources:

- Amplitude Noise in the Laser Output Power
- Laser Phase Noise or Frequency Instability
- Mechanical Thermal Noise in the Antenna
- Radiation-Pressure Noise from the Laser Light
- Seismic Noise
- Thermal-Gradient Noise
- Cosmic-Ray Noise
- Gravitational-Gradient Noise
- Electric Field and Magnetic Field Noise

Vibration Isolation

The Detectors

Advanced LIGO – Advanced Virgo

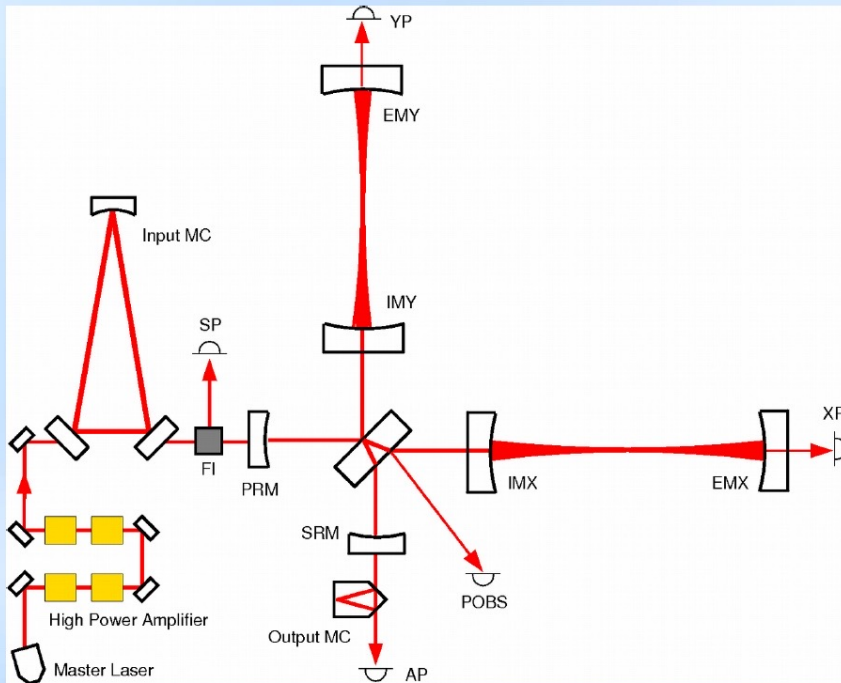

Built on the experience gained from the first generation detectors

Advanced LIGO

- Advanced LIGO commissioned 2010-2015.
 - » Increased laser power
 - » Sophisticated seismic/vibration suppression
 - » Quadruple pendula suspensions
 - » Larger mirrors, better suspension material
 - » More complex and versatile interferometer configuration.

Advanced Virgo

- Larger mirrors; better optical quality.
- Higher finesse of the arm cavities
- Increased laser power.
- Coming on-line in Spring 2017.

Advanced Virgo

Mirror

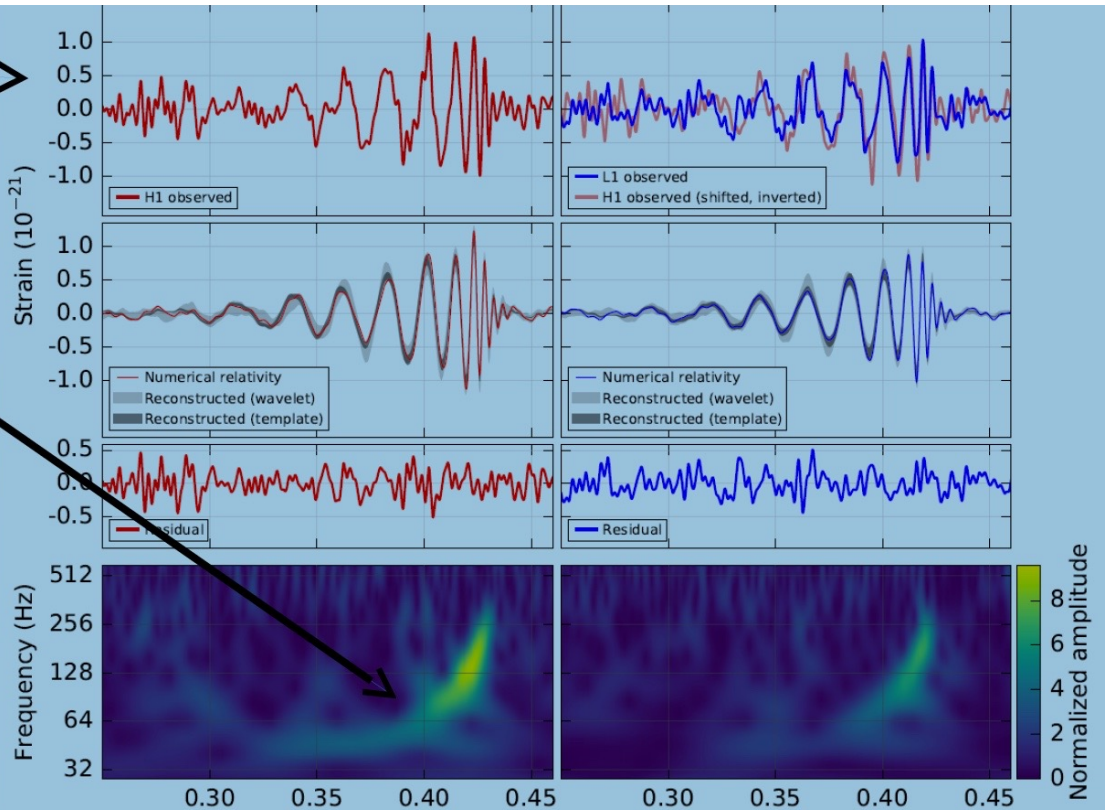

Beamsplitter

The optical components are very large, but their quality is exquisite.

GW150914

- Band-pass filter: 35-350 Hz
- L1-H1 time delay of about 7ms.
- Chirp signal, typical of binary coalescences.
- Detected by online burst-search pipelines.
- Confirmed later matched template searches.
- Combined SNR: 24.

The Results

Observation of Gravitational Waves from a Binary Black Hole Merger

B. P. Abbott *et al.**

(LIGO Scientific Collaboration and Virgo Collaboration)

(Received 21 January 2016; published 11 February 2016)

On September 14, 2015 at 09:50:45 UTC the two detectors of the Laser Interferometer Gravitational-Wave Observatory simultaneously observed a transient gravitational-wave signal. The signal sweeps upwards in frequency from 35 to 250 Hz with a peak gravitational-wave strain of 1.0×10^{-21} . It matches the waveform predicted by general relativity for the inspiral and merger of a pair of black holes and the ringdown of the resulting single black hole. The signal was observed with a matched-filter signal-to-noise ratio of 24 and a false alarm rate estimated to be less than 1 event per 203 000 years, equivalent to a significance greater than 5.1σ . The source lies at a luminosity distance of 410^{+160}_{-180} Mpc corresponding to a redshift $z = 0.09^{+0.03}_{-0.04}$. In the source frame, the initial black hole masses are $36^{+5}_{-4}M_{\odot}$ and $29^{+4}_{-4}M_{\odot}$, and the final black hole mass is $62^{+4}_{-4}M_{\odot}$, with $3.0^{+0.5}_{-0.5}M_{\odot}c^2$ radiated in gravitational waves. All uncertainties define 90% credible intervals. These observations demonstrate the existence of binary stellar-mass black hole systems. This is the first direct detection of gravitational waves and the first observation of a binary black hole merger.

DOI: 10.1103/PhysRevLett.116.061102

Primary black hole mass	$36^{+5}_{-4}M_{\odot}$
Secondary black hole mass	$29^{+4}_{-4}M_{\odot}$
Final black hole mass	$62^{+4}_{-4}M_{\odot}$
Final black hole spin	$0.67^{+0.05}_{-0.07}$
Luminosity distance	410^{+160}_{-180} Mpc
Source redshift z	$0.09^{+0.03}_{-0.04}$

Phenomenology of GW

When GW passes through space deforms it

When GW passes through space deforms it

When GW passes through space deforms it

**But deformations are very small:
strain=relative deformation**

$$h = \Delta L / L \sim 10^{-21}$$

For $L_{\text{Sun-Earth}} \sim 1.5 \times 10^{13} \text{ cm}$

$h L_{\text{Sun-Earth}} \sim 10^{-21} \times 1.5 \times 10^{13} \sim 1.5 \times 10^{-8} \text{ cm}$

size of H atom at distance Sun-Earth

Some math:

Consider Einstein equation

$$R_{\mu\nu} - \frac{1}{2} g_{\mu\nu} R = \frac{8\pi G}{c^4} T_{\mu\nu}$$

Consider a small perturbation of the flat Cartesian metric
Weak field (far from source)

$$g_{\mu\nu} = \eta_{\mu\nu} + h_{\mu\nu} \quad \text{with } |h_{\mu\nu}| \ll 1$$

Using gauge invariance and assuming vacuum ($T=0$ no mass no energy)

Equation of WAVES!!

$$\square h = -\frac{16\pi G}{c^4} T_{\mu\nu} = 0$$

If you want to know more about GR formalism:

<https://arxiv.org/pdf/1607.04202.pdf>

By integrating equation $\square h = -\frac{16\pi G}{c^4} T_{\mu\nu}$

$$h^{ij}(t, \vec{x}) \sim \frac{2G}{r c^4} \frac{d^2}{dt^2} I^{ij}(t - r/c)$$

Distance source-
observer

Moment of inertia,
or second mass
moment, or
quadrupole
moment of mass

Retarded time

$$I^{ij} = \int dx^3 \rho(t, \vec{x}) x^i x^j$$

→ not all accelerating masses do this job but only those with **QUADRUPOLE**

If you do calculation, monopole and dipole disappear

→ for a gravitational wave to form, there must be an **ASYMMETRY IN MASS DISTRIBUTION**

What are the astrophysical objects with non-zero quadrupole?

Primordial gravitational waves / Quantum fluctuations:
 $\ll 1$ sec from Big Bang, due to INFLATION of the Universe
 Freq. $\sim 10^{-16} - 10^2$ Hz
 extremely “faint” (small amplitude)

Mergers of super-massive black holes (SMBHs, $>10^5 M_{\text{sun}}$):

Black holes at centre of galaxies might form Keplerian binaries
and might merge

Freq. $\sim 10^{-10} - 0.1 \text{ Hz}$

Mergers of super-massive black holes (SMBHs, $>10^5 M_{\text{sun}}$):

Black holes at centre of galaxies might form Keplerian binaries
and might merge

Freq. $\sim 10^{-10} - 0.1 \text{ Hz}$

Mergers of compact object binaries (black holes $<10^5 M_{\text{sun}}$, neutron stars):

Black holes (BHs) and neutron stars (NSs) born from stars might merge
Freq. $\sim 10^{-4} - 10^3 \text{ Hz}$

Mergers of SMBHs and stellar-mass BHs:

Small BHs might orbit SMBHs and be captured by them

Freq. $\sim 10^{-4} - 0.1$ Hz

Mergers of SMBHs and stellar-mass BHs:

Small BHs might orbit SMBHs and be captured by them

Freq. $\sim 10^{-4} - 0.1$ Hz

Asymmetric supernova explosions:
Freq. $\sim 10 - 10^2$ Hz

Mergers of super-massive black holes (SMBHs, $>10^5 M_{\text{sun}}$)

Mergers of compact object binaries

Only GWs observed so far

Mergers of SMBHs and BHs

Neutron stars with crustal asymmetries

Asymmetric supernova explosions

Some essential math about GWs from BINARIES:

It can be shown that $h^{ij}(t, \vec{x}) \sim \frac{2G}{r c^4} \frac{d^2}{dt^2} I^{ij}(t - r/c)$

can be expressed in spherical coordinates (r, ϕ, θ)
 for a KEPLERIAN BINARY with reduced mass $\mu = m_1 m_2 / (m_1 + m_2)$
 with semi-major axis a , with orbital frequency ω_{orb}
 and eccentricity $e = 0$ as

$$h_+(t, \theta, \phi, r) = \frac{1}{r} \frac{4G \mu \omega_{orb}^2 a^2}{c^4} \frac{1 + \cos^2 \theta}{2} \cos(2 \omega_{orb} t_{ret} + \phi)$$

$$h_x(t, \theta, \phi, r) = \frac{1}{r} \frac{4G \mu \omega_{orb}^2 a^2}{c^4} \cos \theta \sin(2 \omega_{orb} t_{ret} + \phi)$$

where $t_{ret} = t - r/c$ $\omega_{orb}^2 = \frac{G(m_1 + m_2)}{a^3}$

This equation tells us:

- GWs are POLARIZED (h_+ , h_x)

- FREQUENCY TERM DEPENDS only ON $2 \omega_{\text{orb}}$

→ frequency of GWs $\omega_{\text{GW}} = 2 \omega_{\text{orb}}$

(true for most evolution)

- AMPLITUDE of GWs:

$$h = \frac{1}{2} \sqrt{h_+^2 + h_x^2} = \frac{2 G \mu \omega_{\text{orb}}^2 a^2}{c^4} \frac{1}{r} \sqrt{\frac{(1 + \cos^2 \theta)^2}{4} + \cos^2 \theta}$$

$$h = \frac{1}{2} \sqrt{h_+^2 + h_x^2} = \frac{2 G^2 m_1 m_2}{a c^4} \frac{1}{r} \sqrt{\frac{(1 + \cos^2 \theta)^2}{4} + \cos^2 \theta}$$

– AMPLITUDE of GWs:

$$h = \frac{1}{2} \sqrt{h_+^2 + h_x^2} = \frac{2 G^2 m_1 m_2}{a c^4} \frac{1}{r} \sqrt{\frac{(1 + \cos^2 \theta)^2}{4} + \cos^2 \theta}$$

- * the bigger the amplitude (strain), the easier the detection
- * the farther the binary, the smaller the amplitude
- * the larger the masses, the larger the amplitude
- * the smaller the semi-major axis, the larger the amplitude

Gravitational Wave of Compact Binary Inspiral

$m_1=1.75 \text{ Msun}$, $m_2=2.25 \text{ Msun}$, start $f=150\text{Hz}$, coalescence: $f=635\text{Hz}$

- EMISSION of GWs implies LOSS of ORBITAL ENERGY:

$$E_{orb} = -\frac{G m_1 m_2}{2 a}$$

THE BINARY SHRINKS WHILE EMITTING GWs
TILL IT MERGES

<https://www.youtube.com/watch?v=g8s81MzzJ5c>

- **EMISSION** of GWs implies **LOSS** of **ORBITAL ENERGY**:
THE BINARY SHRINKS WHILE EMITTING GWs
TILL IT MERGES
- If the binary shrinks ($a \rightarrow 0$), frequency becomes higher
- If the binary shrinks amplitude increases

Gravitational Wave of Compact Binary Inspiral

$m_1=1.75 \text{ Msun}$, $m_2=2.25 \text{ Msun}$, start $f=150\text{Hz}$, coalescence: $f=635\text{Hz}$

– EMISSION of GWs implies LOSS of ORBITAL ENERGY:

Power radiated by GWs:

From GR $P_{GW} = \frac{32}{5} \frac{G^4}{c^5} \frac{1}{a^5} m_1^2 m_2^2 (m_1 + m_2)$

$$P_{GW} = \frac{dE_{orb}}{dt} = \frac{G m_1 m_2}{2 a^2} \frac{da}{dt}$$

From Kepler and Newton

→ $\frac{da}{dt} = \frac{64}{5} \frac{G^3}{c^5} a^{-3} m_1 m_2 (m_1 + m_2)$

Integrating differential equation:

$$t_{GW} = \frac{5}{256} \frac{c^5}{G^3} \frac{a^4}{m_1 m_2 (m_1 + m_2)}$$

Timescale for a system to merge by GW emission

For binaries with general eccentricity e

$$t_{GW} = \frac{5}{256} \frac{c^5}{G^3} \frac{a^4 (1 - e^2)^{7/2}}{m_1 m_2 (m_1 + m_2)}$$

Peters 1964

Timescale depends on semi-major axis, eccentricity, masses

Timescale extremely long

EXERCISE: calculate t_{GW} for 2 neutron stars
with mass equal to the Sun mass (1 Msun)
orbiting at the distance
between Sun and Earth (1 AU)

$$a(t) = a_0 \left[1 - \frac{256/5 G^3 m_1 m_2 (m_1 + m_2) t}{c^5 (1 - e^2)^{7/2} a_0^4} \right]^{1/4}$$

Previous equations are not always true!

Only before merger when binary can be considered Keplerian

i.e. only during inspiral

Templates for GWs from BBH coalescence

(Brady, Craighton, Thorne 1998)

(Buonanno & Damour 2000)

Numerical Relativity, the 2005 breakthrough:
Pretorius, Campanelli et al., Baker et al. ...

NUMERICAL RELATIVITY WAVEFORM

Numerical Relativity: ≥ 2005 (Pretorius, Campanelli et al., Baker et al.)

Very accurate data: Caltech-Cornell spectral code (with some caveats): M. Scheel et al., 2008

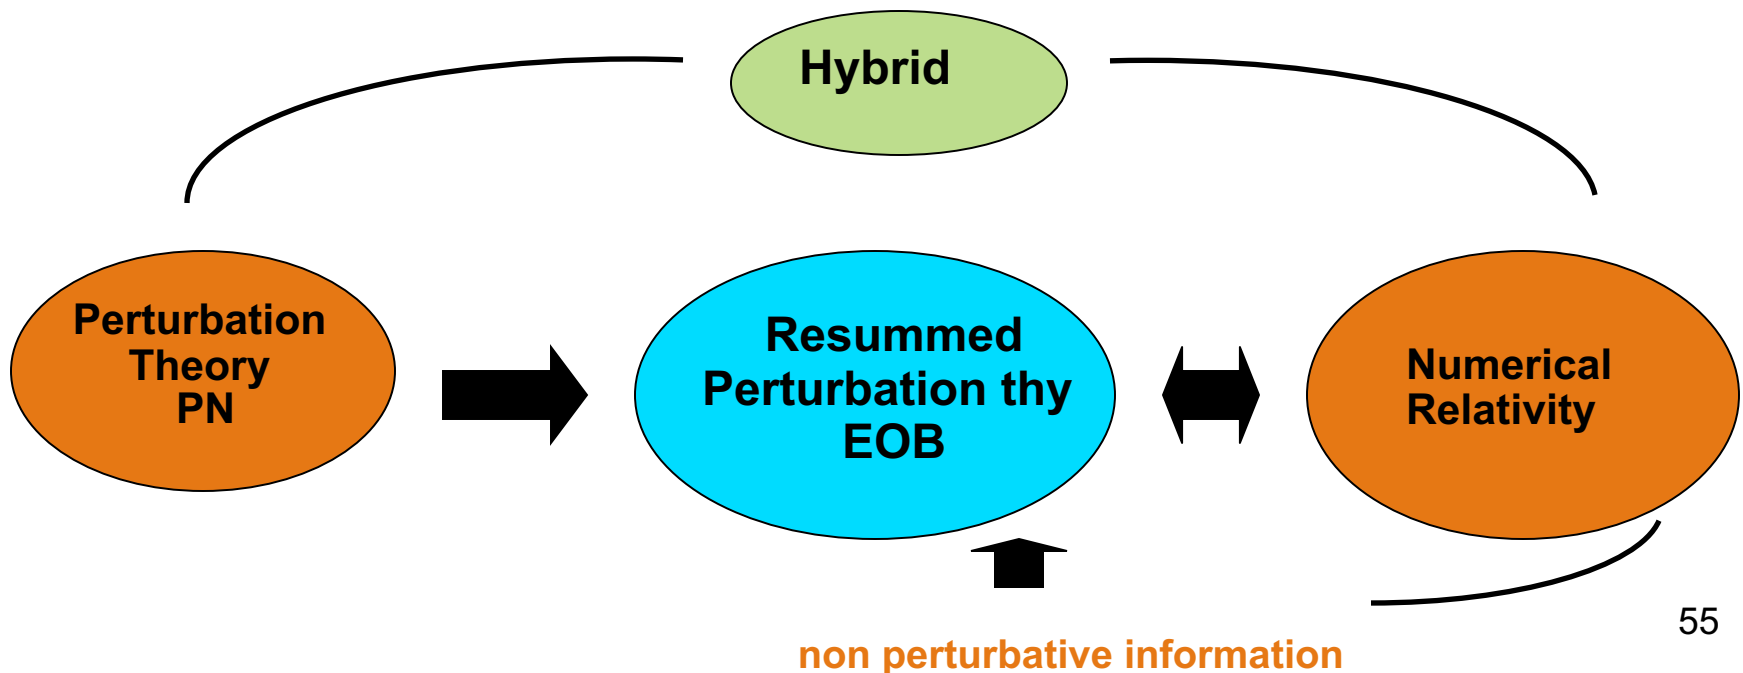

Spectral code

Extrapolation (radius & resolution) Phase error: < 0.02 rad (inspiral) < 0.1 rad (ringdown)

Importance of an analytical formalism

- **Theoretical:** physical understanding of the coalescence process, especially in complicated situations (arbitrary spins)
- **Practical:** need many thousands of accurate GW templates for detection & data analysis; need some “analytical” representation of waveform templates as $f(m_1, m_2, \mathbf{S}_1, \mathbf{S}_2)$
- Solution: **synergy between analytical & numerical relativity**

EFFECTIVE ONE BODY (EOB) approach to the two-body problem

Taylor-expanded 3PN waveform

Blanchet, Iyer, Joguet 02, Blanchet, Damour, Esposito-Farese, Iyer 04, Kidder 07, Blanchet et al. 08

$$\begin{aligned} h^{22} = & -8\sqrt{\frac{\pi}{5}} \frac{G\nu m}{c^2 R} e^{-2i\phi} x \left\{ 1 - x \left(\frac{107}{42} - \frac{55}{42} \nu \right) + x^{3/2} \left[2\pi + 6i \ln\left(\frac{x}{x_0}\right) \right] - x^2 \left(\frac{2173}{1512} + \frac{1069}{216} \nu - \frac{2047}{1512} \nu^2 \right) \right. \\ & - x^{5/2} \left[\left(\frac{107}{21} - \frac{34}{21} \nu \right) \pi + 24i\nu + \left(\frac{107i}{7} - \frac{34i}{7} \nu \right) \ln\left(\frac{x}{x_0}\right) \right] \\ & + x^3 \left[\frac{27\,027\,409}{646\,800} - \frac{856}{105} \gamma_E + \frac{2}{3} \pi^2 - \frac{1712}{105} \ln 2 - \frac{428}{105} \ln x \right. \\ & \left. \left. - 18 \left[\ln\left(\frac{x}{x_0}\right) \right]^2 - \left(\frac{278\,185}{33\,264} - \frac{41}{96} \pi^2 \right) \nu - \frac{20\,261}{2772} \nu^2 + \frac{114\,635}{99\,792} \nu^3 + \frac{428i}{105} \pi + 12i\pi \ln\left(\frac{x}{x_0}\right) \right] + O(\epsilon^{7/2}) \right\}, \end{aligned}$$

$$x = (M\Omega)^{2/3} \sim v^2/c^2$$

$$M = m_1 + m_2$$

$$\nu = m_1 m_2 / (m_1 + m_2)^2$$

**Simple way to estimate frequency at merger:
Last stable circular orbit around a black hole**

$$r_{\text{LSCO}} = 6 \frac{G (m_1 + m_2)}{c^2}$$

$$\omega_{\text{GW,LSCO}} = 2 \sqrt{\frac{G (m_1 + m_2)}{r_{\text{LSCO}}^3}} = \frac{2 c^3}{6^{3/2} G (m_1 + m_2)}$$

$$\omega_{\text{GW,LSCO}} = 460 \text{ Hz} \frac{60 M_{\text{sun}}}{(m_1 + m_2)}$$

Abbott et al. 2016

Detectors:

Advanced LIGO (Livingstone + Hanford, US)

Advanced Virgo (Pisa, Italy)

LIGO Lab/Virgo

Michelson interferometers

Design started in the '90s

First science runs ~ 2007 (no detection)

Being upgraded in 2007 – 2015

First run advanced detectors 2015

Time schedule

Frequency range: $\sim 10 - 10,000$ Hz

Suitable for mergers of compact binaries

- Early
- Mid
- Late
- Design

**Noise level of LIGO & Virgo
(Noise power spectral density)**

Summary of detections:

2015/09/12	first LIGO run	
2015/09/14	GW150914	black holes (BHs)
2015/10/12	LVT151012	maybe BHs
2015/12/26	GW151226	BHs
2015/01 – 2016/11	detectors switched off	
2017/01/04	GW170104	BHs
2017/08/01	Virgo joins LIGO	
2017/08/14	GW170814	BHs
2017/08/17	GW170817	neutron stars (NSs)
2017/08/25 – now	detectors switched off

Space missions

Laser Interferometer Space Antenna - LISA

Present plan: 3 Interferometers
 2.5×10^6 km arm lengths

ESA – All Systems GO!

Recent “Call” for mission

Acceptance - soon?

Planned launch 2034

NASA coming back

Earlier launch? 2028?

LIGO GW events and
Lisa Pathfinder success
have helped significantly

Tremendous activity at
present

LISA in Orbit

LISA physics

- the nature of gravity
- the fundamental nature of black holes
- black holes as sources of energy
- nonlinear structure formation
- dynamics of galactic nuclei
- formation and evolution of stellar binary systems
- the very early universe
- cosmography (specifically, the cosmic distance scale)

Gravitational Observatory Advisory Team – GOAT (ESA web site)

LISA Pathfinder – Demonstrating LISA Technology

LISA Pathfinder worked! Exceeded requirements. Still, operation was not perfect, and there is lots of experimental work to do before LISA.

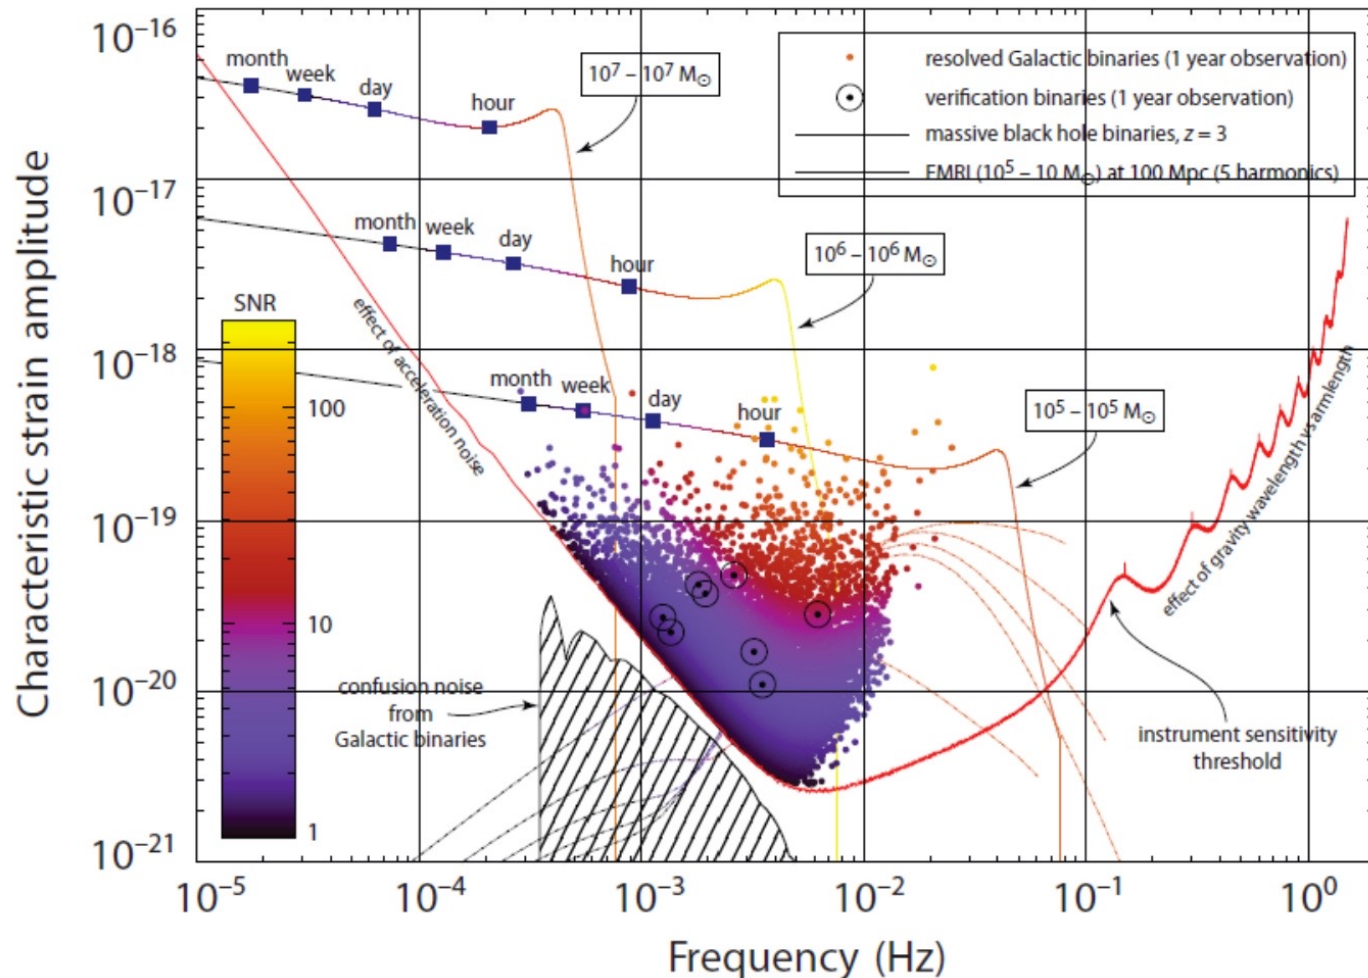

A set of cold gas micro-newton thrusters to ensure the spacecraft follows TM1. A second control loop forces TM2 to stay at a fixed distance from TM1 and thus centered in its own electrode housing.

LISA Proof Masses, Optical Bench, Interferometry and Telescopes

LISA Physics

LISA GOAT

61

Characteristic strain amplitude versus frequency for a space-based laser interferometry mission (arm length 10^6 km, 1-yr observations). Objects expected to be strong gravitational wave sources over this frequency range.

Testing the Early Universe

- Inflation
- Electro-weak phase transition, or phase transitions related to new physics
- Cosmic strings (phase transitions, topological defects, cosmic superstrings)

		Source			
		ultra-compact binaries	astrophysical black holes	extreme mass-ratio inspirals	background (astrophysical/cosmological)
Scientific topic	nature of gravity				
	fundamental nature of black holes				
	black holes as sources of energy				
	nonlinear structure formation				
	dynamics of galactic nuclei				
	formation/evolution of stellar binary systems				
	very early Universe				
	cosmography				

LISA Summary

The LISA project is presently moving forward rapidly.

ESA and NASA see this as a high priority.

A tremendous amount of R&D still needs to be done for LISA, and there is much experimental activity.

After the LHC, LISA may offer the best opportunity to observe the high energy physics that describes the universe.

Pulsar Timing Arrays

Idea: use pulsars as clocks

Opportunities for detecting ultralong gravitational waves

M. V. Sazhin

Shternberg Astronomical Institute, Moscow

(Submitted June 14, 1977)

Astron. Zh. **55**, 65–68 (January–February 1978)

The influence of ultralong gravitational waves on the propagation of electromagnetic pulses is examined. Conditions are set forth whereby it might be possible to detect gravitational waves arriving from binary stars. There are some prospects for detecting gravitational radiation from double superstars with masses $\mathfrak{M}_1 \approx \mathfrak{M}_2 \approx 10^{10} \mathfrak{M}_{\odot}$.

PACS numbers: 97.80.—d, 97.60.Gb, 95.30.Gv

Spin-Powered Pulsars: A Census

- Number of known pulsars: 1765
- Number of millisecond pulsars: 170
- Number of binary pulsars: 131
- Number of AXPs: 12
- Number of pulsars in globular clusters: 99*
- Number of extragalactic pulsars: 20

* Total known: 129 in 24 clusters (Paulo Freire's web page)

Data from ATNF Pulsar Catalogue, V1.25
(www.atnf.csiro.au/research/pulsar/psrcat; Manchester et al. 2005)

P - Ṗ Diagram

- Millisecond pulsars have very low P and are very old
- Most MSPs are binary
- MSPs are formed by 'recycling' an old pulsar in an evolving binary system
- 'Normal' pulsars have significant period irregularities, but MSP periods are very stable

Pulsars and Gravitational Waves

Orbital decay in high-mass short-period binary systems accounted for by loss of energy to gravitational waves.

First observational evidence for gravitational waves!

Observed rates agree with the predictions of general relativity!

- PSR B1913+16: $\dot{P}_{b,obs}/\dot{P}_{b,pred} = 1.0013 \pm 0.0021$

Precision of GR test limited by uncertainty in correction for acceleration in gravitational field of the Galaxy (Weisberg & Taylor 2005)

- PSR B1534+12: $\dot{P}_{b,obs}/\dot{P}_{b,pred} = 0.91 \pm 0.05$

Limited by uncertainty in pulsar distance; assuming GR gives improved distance estimate (Stairs et al. 2002)

- PSR J1141-6545: $P_{b,obs}/P_{b,pred} = 1.05 \pm 0.25$

(NS-WD system) (Bailes et al. 2003)

- PSR J0737-3039A/B: $P_{b,obs}/P_{b,pred} = 1.004 \pm 0.014$

Expect 0.1% test in ~5 years! (Kramer et al. 2006)

PSR J0737-3039A/B - the Double Pulsar

- Four times as relativistic as Hulse-Taylor binary pulsar
- Detection of both pulsars gives the mass ratio of the two stars
- Have measured five relativistic parameters in just two years!
- Four independent tests of general relativity
- Consistent at the 0.05% level!

R: Mass ratio

ω : periastron advance

γ : gravitational redshift

r & s: Shapiro delay

P_b : orbit decay

(Kramer et al. 2006)

Pulsar limits on the GW Background

- Gravitational waves (GW) passing over the pulsar and the Earth perturb the apparent pulse period
- Results in additional 'noise' in pulse arrival times (TOAs) and hence increased scatter in timing residuals (differences between observed and predicted TOAs)
- If no signal detected, can set a limit on strength of GW background
- Best limits are obtained for GW frequencies $\sim 1/T$ where T is length of data span
- Analysis of 8-year sequence of Arecibo observations of PSR B1855+09 gives $\Omega_{\text{gw}} = \rho_{\text{gw}}/\rho_c < 10^{-7}$ (Kaspi et al. 1994, McHugh et al. 1996)
- Extended 17-year data set gives better limit, but non-uniformity makes quantitative analysis difficult (Lommen 2001)

A Pulsar Timing Array

- With observations of many pulsars widely distributed on the sky can in principle **detect** a stochastic gravitational wave background
- Gravitational waves passing over Earth produce a **correlated** signal in the TOA residuals for all pulsars
- Gravitational waves passing over the pulsars are uncorrelated
- Requires observations of ~20 MSPs over 5 – 10 years;
- A timing array can detect instabilities in terrestrial time standards – establish a **pulsar timescale**
- Can improve knowledge of Solar system properties, e.g. masses and orbits of outer planets and asteroids

Idea first discussed by Foster & Backer (1990)

➤ **Clock errors**

All pulsars have the same TOA variations: **monopole** signature

➤ **Solar-System ephemeris errors**

Dipole signature

➤ **Gravitational waves**

Quadrupole signature

Can separate these effects provided there is a sufficient number of widely distributed pulsars

Detecting a Stochastic GW Background

Simulation using Parkes Pulsar Timing Array (PPTA) pulsars with GW background from binary black holes in galaxies

(Rick Jenet, George Hobbs)

The Parkes Pulsar Timing Array Project

Collaborators:

- Australia Telescope National Facility, CSIRO
Dick Manchester, George Hobbs, Russell Edwards, John Sarkissian, John Reynolds, Mike Kesteven, Grant Hampson, Andrew Brown
- Swinburne University of Technology
Matthew Bailes, Ramesh Bhat, Joris Verbiest, Albert Teoh
- University of Texas, Brownsville
Rick Jenet, Willem van Straten
- University of Sydney
Steve Ord
- National Observatories of China, Beijing
Xiaopeng You
- Peking University, Beijing
Kejia Lee
- University of Tasmania
Aidan Hotan

The PPTA Project: Goals

- To detect gravitational waves of astrophysical origin
- To establish a pulsar-based timescale and to investigate irregularities in terrestrial timescales
- To improve on the Solar System ephemeris used for barycentric correction
- Modelling and detection algorithms for GW signals
- Measurement and correction for interstellar and Solar System propagation effects
- Investigation and implementation of methods for real-time RFI mitigation

To achieve these goals we need ~weekly observations of ~20 MSPs over at least five years with TOA precisions of ~100 ns for ~10 pulsars and $< 1 \mu\text{s}$ for rest

The PPTA Project: Methods

- Using the Parkes 64-m telescope at three frequencies (680, 1400 and 3100 MHz)
- Digital filterbank system, 256 MHz bandwidth (1 GHz early 2007), 8-bit sampling, polyphase filter
- CPSR2 baseband system 2 x 64 MHz bandwidth, 2-bit sampling, coherent de-dispersion
- Developing APSR with 512 MHz bandwidth and 8-bit sampling
- Implementing real-time RFI mitigation for 50-cm band
- TEMPO2: New timing analysis program, systematic errors in TOA corrections < 1 ns, graphical interfaces, predictions and simulations (Hobbs et al. 2006, Edwards et al. 2006)
- Observing 20 MSPs at 2 - 3 week intervals since mid-2004
- Looking to international co-operation to obtain improved data sampling including pulsars at northern declinations

Sky Distribution of Millisecond Pulsars

$P < 20$ ms and not in globular clusters

PPTA Pulsars

- 20 MSPs - all in Galactic disk except J1824-2452 (B1821-24) in M28
- Two years of timing data at 2 -3 week intervals and at three frequencies
- Uncorrected for DM variations and polarisation calibration
- Five pulsars with rms timing residuals < 500 ns, all < 2.5 μ s
- Best results on J0437-4715 (120 ns) and B1937+21 (170 ns)

Name	Period (ms)	DM (cm^{-3} pc)	Orbital period (d)	Rms Residual (μ s)

J2145-0750	16.052	9.00	6.84	1.44

Still have a way to go!

Dispersion Measure Variations

- ΔDM from 10/50cm or 20/50cm observation pairs
- Variations observed in most of PPTA pulsars
- ΔDM typically a few $\times 10^{-3} \text{ cm}^{-3} \text{ pc}$
- Weak correlation of $d(DM)/dt$ with DM , closer to linear rather than $DM^{1/2}$
- Effect of Solar wind observed in pulsars with low ecliptic latitude

(You et al.,)

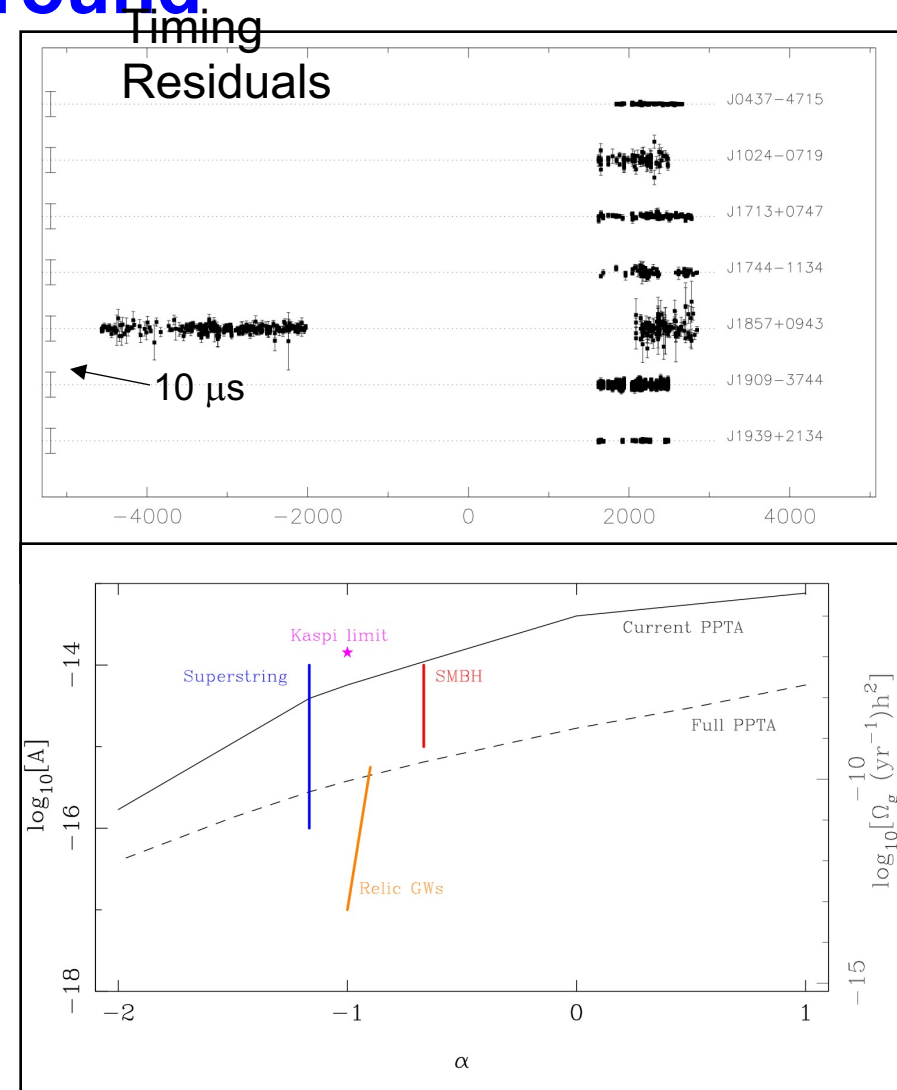

The Gravitational Wave Spectrum

Current and Future Limits on the Stochastic GW Background

- Arecibo data for PSR B1855+09 (Kaspi et al. 1994) combined with subset of recent PPTA data
- Monte Carlo methods used to determine detection limit for stochastic background described by $h_c = A(f/1\text{yr})^\alpha$ (where $\alpha = -2/3$ for SMBH, ~ -1 for relic radiation, $\sim -7/6$ for cosmic strings)
- Current limit: $\Omega_{\text{gw}}(1/8 \text{ yr}) \sim 2 \times 10^{-8}$
- For full PPTA (100ns, 5 yr): $\sim 10^{-10}$
- Currently consistent with all SMBH evolutionary models
- If no detection with full PPTA, all current models ruled out
- Already limiting EOS of matter in epoch of inflation and tension in cosmic strings

(Jenet et al. 2006)

NANOGrav

$$S(f) = \frac{A_{\text{CP}}^2}{12\pi^2} \left(\frac{f}{f_{\text{yr}}} \right)^{-\gamma} f_{\text{yr}}^{-3},$$

Summary pulsars

- Direct detection of gravitational waves (GW) is a major goal of current astrophysics - it will open a new window on the Universe
- A pulsar timing array can **detect** GW from astrophysical sources
- Pulsars are sensitive to GW at nHz frequencies - complementary to ground-based and space-based laser-interferometer systems
- Parkes Pulsar Timing Array (PPTA) timing 20 MSPs since mid-2004. Goal is ~ 100 ns time residuals on at least half of sample, currently have five with rms residuals < 500 ns
- Current data improve the limit on the stochastic GW background by a factor of five. Full PPTA should detect the predicted background
- Expect pulsar-based timescale to have better long-term stability than current best terrestrial timescales
- SKA will herald a new era in the study of gravitational waves!

*GW from Primordial
Magnetic Field at QCD
phase transition*

Pulsar timing arrays

$$S(f) = \frac{A_{\text{CP}}^2}{12\pi^2} \left(\frac{f}{f_{\text{yr}}} \right)^{-\gamma} f_{\text{yr}}^{-3},$$

$$h_c(f) = \sqrt{12\pi^2 S(f) f^3} = A_{\text{CP}} \left(\frac{f}{f_{\text{yr}}} \right)^{\frac{3-\gamma}{2}}$$

$$\Omega_{\text{GW}}^0(f) = \Omega_{\text{yr}} \left(\frac{f}{f_{\text{yr}}} \right)^{\beta},$$

$$\Omega_{\text{yr}} = \frac{2\pi^2}{3H_0^2} f_{\text{yr}}^2 A_{\text{CP}}^2, \quad \beta = 5 - \gamma.$$

Inter-Galactic Magnetic Field detection with gamma-rays

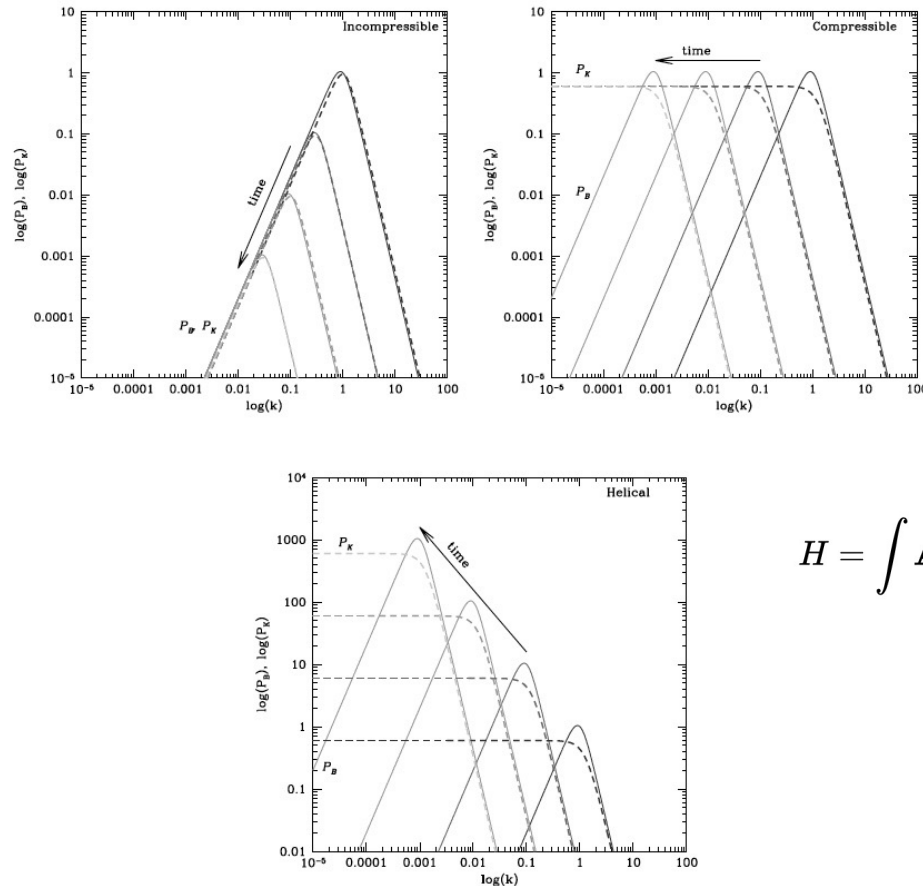

Primordial magnetic field and cosmological model

Produced spectrum of PMF

From R.Durrer and A.Neronov, A&A Rev. 21 62, [1303.7121].

Early Universe evolution of spectrum of PMF

$$H = \int \mathbf{A} \cdot \mathbf{B} d^3 \mathbf{r}$$

PMF from inflation and phase transitions

$$\mathcal{P}_B(\tau_0, k) \lesssim (10^{-15} \text{ G})^2 \left(\frac{k}{a_0} \text{ Mpc} \right)^2 \left(\frac{H_{\text{reh}}}{H_{\text{inf}}} \right)^{1/3} \frac{10^{-14} \text{ GeV}}{H_{\text{inf}}}. \quad (3.20)$$

For classical scenarios we obtained the bound (3.20), which requires an extremely low scale inflation of $H_{\text{inf}} \lesssim 10^{-19} \text{ GeV}$ (3.22) in order for magnetic fields of 10^{-15} G to be produced on Mpc scales or larger without spoiling the cosmological perturbations. Thus unless reheating and baryogenesis happen within a very narrow temperature window of $5 \text{ MeV} \lesssim T_{\text{reh}} \lesssim 10^2 \text{ MeV}$, classical scenarios cannot produce the intergalactic magnetic fields suggested by gamma ray observations.

Quantum mechanical scenarios were found to be even more restricted; in cases where the quantum vector fluctuations smoothly convert into classical fluctuations, our result (4.15) shows that the produced magnetic fields cannot exceed 10^{-43} G on Mpc or larger scales, independently of the inflation scale. Even with non-smooth quantum to classical transitions (such as in resonant production), as long as the condition (4.23) is satisfied, the constraints on quantum mechanically produced magnetic fields are at least as strong as the constraint for classical scenarios.

MF before EW phase transition

1. INTRODUCTION

On February 23.316 UT, 1987, light and neutrinos from the brightest
supernova in 383 years arrived at Earth, shocking astrophysicists into a
frenzied state of activity. Since that time Supernova 1987A (SN 1987A)
has taken its place as one of the most thoroughly studied objects inside the solar system.
Detected by instruments on the ground, below the ground, in space,
and from all continents, including Antarctica. Studied at all wavelengths from radio
through gamma rays, SN 1987A is the only object besides the Sun to have
been detected in neutrinos. From these extensive observations has emerged

Abstract

On 2017 August 17 a binary neutron star coalescence candidate (later designated GW170817) with merger time 12:41:04 UTC was observed through gravitational waves by the Advanced LIGO and Advanced Virgo detectors. The Fermi Gamma-ray Burst Monitor independently detected a gamma-ray burst (GRB 170817A) with a time delay of ~ 1.7 s with respect to the merger time. From the gravitational-wave signal, the source was initially localized to a sky region of 31 deg^2 at a luminosity distance of 40^{+8}_{-14} Mpc and with component masses consistent with neutron stars. The component masses were later measured to be in the range 0.86 to $2.26 M_{\odot}$. An extensive observing campaign was launched across the electromagnetic spectrum leading to the discovery of a bright optical transient (SSS17a, now with the IAU identification of AT 2017gfo) in NGC 4993 (at ~ 40 Mpc) less than 11 hours after the merger by the One-Meter, Two Hemisphere (IM2H) team using the 1 m Swope Telescope. The optical transient was independently detected by multiple teams within an hour. Subsequent observations targeted the object and its environment. Early ultraviolet observations revealed a blue transient that faded within 48 hours. Optical and infrared observations showed a redward evolution over ~ 10 days. Following early non-detections, X-ray and radio emission were discovered at the transient's position ~ 9 and ~ 16 days, respectively, after the merger. Both the X-ray and radio emission likely arise from a physical process that is distinct from the one that generates the UV/optical/near-infrared emission. No ultra-high-energy gamma-rays and no neutrino candidates consistent with the source were found in follow-up searches. These observations support the hypothesis that GW170817 was produced by the merger of two neutron stars in NGC 4993 followed by a short gamma-ray burst (GRB 170817A) and a kilonova/macronova powered by the radioactive decay of r -process nuclei synthesized in the ejecta.

Key words: gravitational waves – stars: neutron

1. Introduction

Over 80 years ago Baade & Zwicky (1934) proposed the idea of neutron stars, and soon after, Oppenheimer & Volkoff (1939) carried out the first calculations of neutron star models. Neutron stars entered the realm of observational astronomy in the 1960s by providing a physical interpretation of X-ray emission from

Heuvel 1975; Mashevitch et al. 1976; Clark 1979; Clark et al. 1979; Dewey & Cordes 1987; Lipunov et al. 1987; for reviews see Kalogera et al. 2007; Postnov & Yungelson 2014). The Hulse-Taylor pulsar provided the first firm evidence (Taylor & Weisberg 1982) of the existence of gravitational waves (Einstein 1916, 1918) and sparked a renaissance of observational tests of general relativity (Damour & Taylor 1991, 1992;

Decline faster in the blue band, 1.5 mag/day

SED shifts from near-UV to near-IR in 8 days – **hot ejecta and rapid cooling**

Kilonova model (r-process)

Lattimer et al, Astrophys. J., 1977

Eichler et al, Nature 1989

Li & Paczynsky, Astrophys. J. 1998

Inferring the kilonova model

- Best fit has three components
 - Lanthanide-poor (blue, $0.5 \text{ cm}^2/\text{g}$), intermediate (magenta, $3 \text{ cm}^2/\text{g}$) and lanthanide-rich (red, $10 \text{ cm}^2/\text{g}$)
- Good fit provides evidence for heavy-element nucleosynthesis and ejection
 - Supernova models (^{56}Ni decay, Fe opacity) do not fit

$$M_{ej} \sim 0.02 M_{\odot}$$

$$v_{ej} \sim 0.26 c$$

$$M_{ej} \sim 0.04 M_{\odot}$$

$$v_{ej} \sim 0.15 c$$

$$M_{ej} \sim 0.01 M_{\odot}$$

$$v_{ej} \sim 0.14 c$$

Kilonova – Nucleosynthesis (1)

Kilonova – Nucleosynthesis (2)

16 000 M_{\oplus}
of heavy elements

10 M_{\oplus}
in gold and platinum
(according to Edo
Berger)

Main discoveries (3)

So far, no convincing global model

X-ray and radio counterparts are likely afterglows (synchrotron)

A. Jet off-axis by ~ 5 deg \rightarrow excluded

- 1.7 s delay is too short (delay to medium transparency)
- Delayed X-rays require viewing angle ~ 13 deg
- Radio flux x 10 larger if true

B. Structured jet (same conclusion)

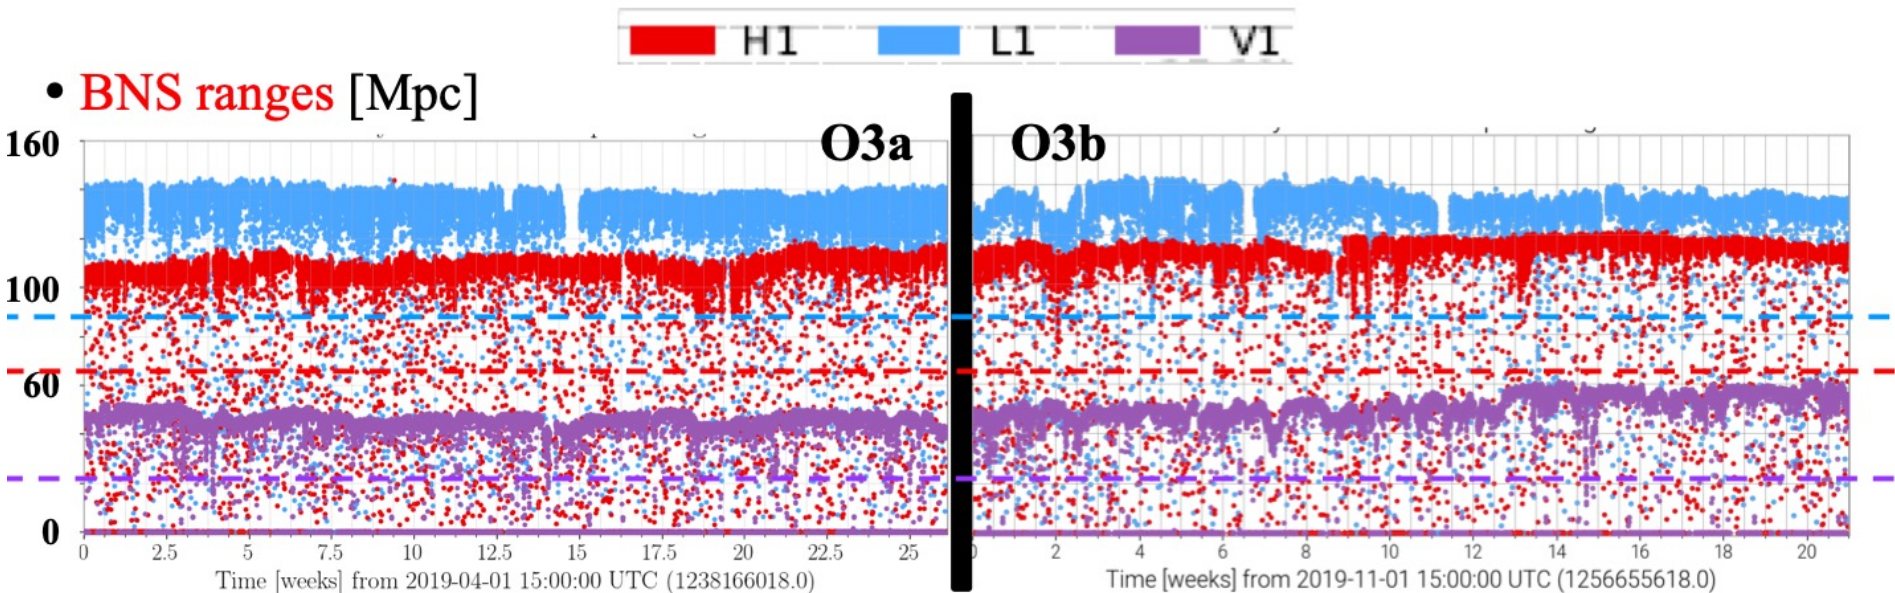

C. "Hot cocoon"

- Kilonova shows that a lot of material surrounds the binary. Jet drills into the ejecta.

Run 03

2018-2019

O3 performance: sensitivity

→ Dashed lines show the corresponding O2-averaged BNS ranges

▪ **LIGO Livingston is the most sensitive detector**, ahead of LIGO Hanford and Virgo

• **Significant progress during the commissioning break for LIGO Hanford and Virgo**

▪ **Point absorbers on optics for LIGO Livingston**

→ **Part of the lost BNS range recovered by tuning instrument**

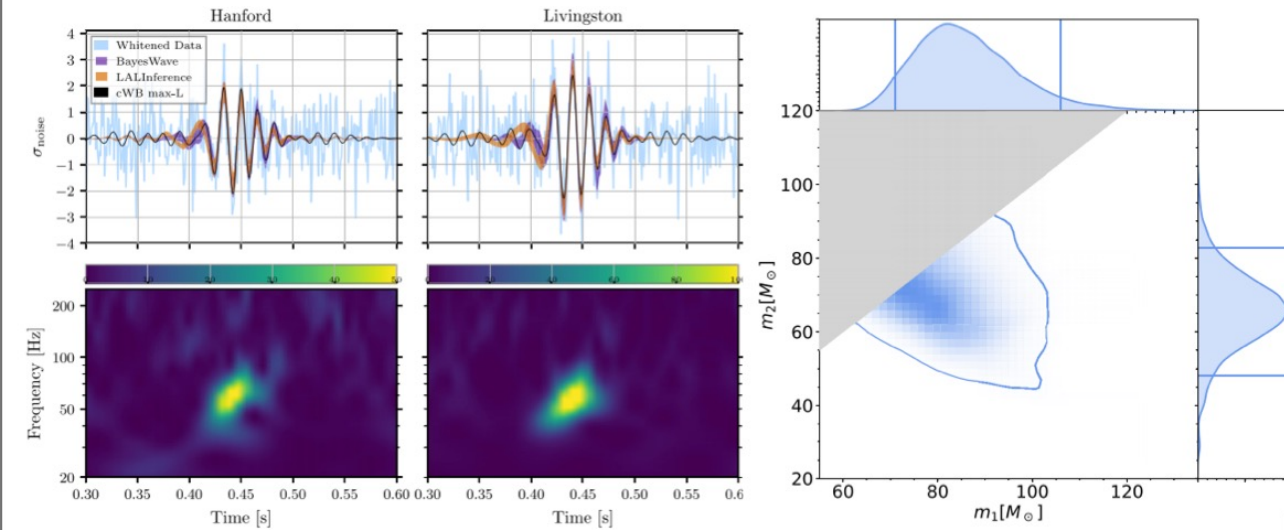

LIGO-Virgo candidate events over time

O3: 1 April 2019 — 27 March 2020

McIver & Shoemaker, in prep.

Many noteworthy transient GW signals discovered in O3

GW190521: 85, 66 M_\odot system \Rightarrow 150 M_\odot
 PISN mass gap: ~ 65 -120 M_\odot
 Abbott, et al., PRL **125** 101102

GW190814: 23, 2.6 M_\odot system
 Uncertain nature of companion
 Abbott, et al., ApJL **896** L44

GW190421: 30, 8 M_\odot system
 Higher order modes
 Abbott, et al., PRD **102** 043015

GW190425: second BNS detection
 Total mass inconsistent with other
 galactic binary NSs
 Abbott, et al., ApJL **892** L3

GWTC-2: 39 new confident detections

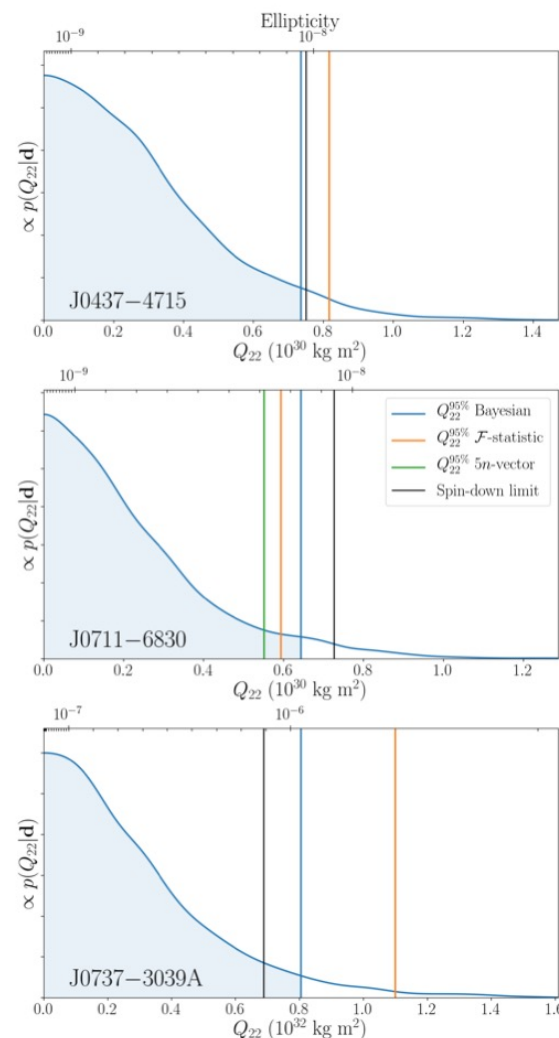

Mass ratio vs. total mass

Recent results for continuous wave searches

Surpassing spindown limit of millisecond pulsars

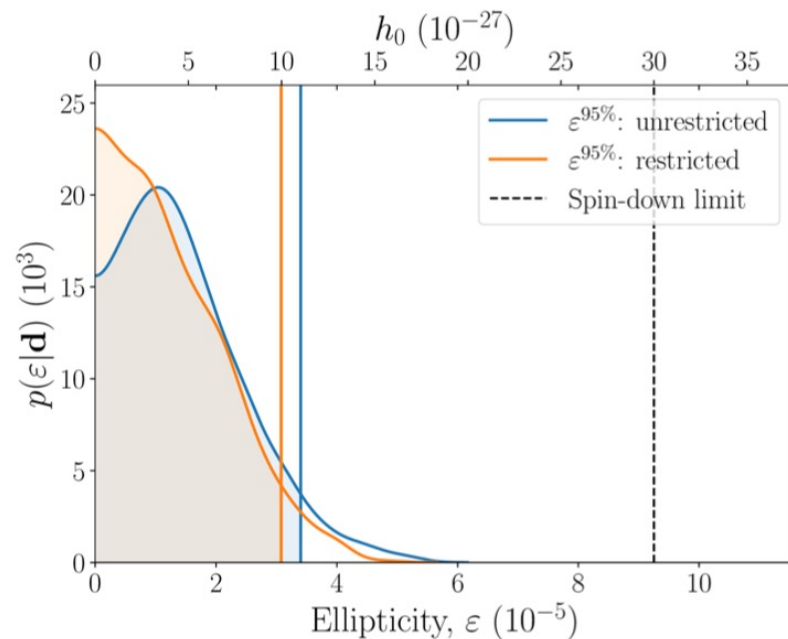

- Spindown limit benchmark for GW emission amplitude from known NSs
- First time spindown limit surpassed for millisecond pulsars
- MSPs have significantly different evolutionary history than slowly rotating pulsars
- Implications for internal magnetic field strength

Recent results for continuous wave searches

Constraining continuous GW emission from J0537-6910

- Large spin down luminosity and frequent pulsar glitches observed
- NICER timing solution + LIGO/Virgo data ==> surpass spindown limit for first time

Recent results for continuous wave searches

All-sky search for unknown neutron stars in binary systems

- Notoriously computationally challenging search to include the additional unknown binary orbital parameters
- Most constraining results to date and probing sources in Galactic neighborhood

Masses in the Stellar Graveyard

in Solar Masses

GWTC-2 plot v1.0

LIGO-Virgo | Frank Elavsky, Aaron Geller | Northwestern

Conclusions

- Exceptional observation campaign after an exceptional event
 - Comprehensive picture of what happened after the merger
- Amazing predictive power of Physics (and physicists!)
 - All electromagnetic counterparts predicted
 - Kilonova (observed timescale, luminosity, color – consistent with simulations)
 - This is no the end of the story: explain gamma-rays vs X-ray and radio observations
- 30 yrs after SN1987A, entering the **golden ages of multimessenger astronomy?**
 - 80 papers published on GW170817 so far (and counting)
<https://lco.global/~iarcavi/kilonovae.html>

Summary

- *99 years after prediction by Einstein, gravitational waves was detected from 2 black holes merger in 2015.*
- *In 2017 extraordinary event of binary NS merger proved heavy element production and challenge gamma-ray models.*
- *This field has great future, first detection just started.*

SEMINAR

For binaries with general eccentricity e

$$t_{GW} = \frac{5}{256} \frac{c^5}{G^3} \frac{a^4 (1 - e^2)^{7/2}}{m_1 m_2 (m_1 + m_2)}$$

Peters 1964

Timescale depends on semi-major axis, eccentricity, masses

Timescale extremely long

EXERCISE: calculate t_{GW} for 2 neutron stars
with mass equal to the Sun mass (1 Msun)
orbiting at the distance
between Sun and Earth (1 AU)

NS-NS merging time

$$G = 6.67 \cdot 10^{-11} \text{ m}^3/\text{kg}/\text{s}^2$$

$$1 \text{ au} = 150 \text{ Mkm} = 1.5 \cdot 10^{11} \text{ m}$$

$$c = 300\,000 \text{ km/s} = 3 \cdot 10^8 \text{ m/s}$$

$$M = M_{\text{sun}} = 10^{33} \text{ g} = 10^{30} \text{ kg}$$

$$G \cdot M / c^2 / a = 6.7 \cdot 10^{-11} \cdot 10^{30} / 9 / 10^{16} / 1.5 \cdot 10^{11} \\ \text{m}^3/\text{s}^2 / \text{m}^3 \cdot \text{s}^2$$

$$G \cdot M / c^2 / a = 5 \cdot 10^{-9}$$

$$T = 5/256/2 \cdot 1.5 \cdot 10^{11} / 3 \cdot 10^8 / (5 \cdot 10^{-9})^3 \text{ sec} = 5 \cdot 10^{24} \\ \text{sec} = 1.5 \cdot 10^{18} \text{ yr} \gg t_U$$
